The Bishop of Gloucester takes alarm unnecessarily. The control of the University can hardly be said to be in the hands of outside members when the Senate has a majority on the Council. It is, indeed, recommended that the University should examine the governing instruments of the present schools. But it is not at all likely to object to them in any important detail since it has already examined them before the schools were admitted. Nor is it at all more likely to be unsympathetic to schools which wish to appeal for money than it is now. Why should it? The schools do not appeal for the fun of the thing, but for real needs, and the needs of education will always be the chief interest of the University. At the present moment the schools do not appeal to the L.C.C. except by the leave of the University. He adds that the University may claim to appoint principal teachers in the schools. It does that now. All Professors and Readers are appointed by the University, and that the Medical Schools, at any rate, appreciate this is shown by the fact that (excluding University and King's) they have now over 30 University Professors, whereas before the war there was not one. I can answer for it that a non-medical school with which I am connected will get as many University Professors as it can afford to pay. Why the Theological Colleges will be in any worse position than they are now I have no idea.

It seems to be suggested that the system of appointment of professors will be changed. Why should it?

Why Dr. Graham Little should suppose that the four members of Council appointed by the Crown, and the two members appointed by the L.C.C. will be appointed for political considerations, I do not know. Exactly the same number are appointed now to the Senate, and I never heard that accusation made of those appointments. Nor do I see what the Mayor of Chicago has to do with the question.

I am, Sir, yours faithfully,

Nov. 29th, 1926. W. P. HERRINGHAM.

THE DISSOLUTION OF INSULIN.

To the Editor of THE LANCET.

SIR,—Prof. Funk's letter in your last issue must be of great interest to all workers with insulin in this country, as it is the first account, apart from incomplete and therefore uninformed newspaper ones, of his recent new work. Unfortunately, however, his letter would appear to have suffered in the translation, because the third paragraph describing his substance is disappointingly obscure, to me at any rate. As far as I can make out, this substance A reduces the blood-sugar of normal rabbits if the fasting level is high, but has no effect or even raises the blood-sugar if the fasting level is low.

Similar results have been obtained in rabbits by Dr. Buckley and myself, working with the ordinary whole insulin (A.B.) produced commercially by The British Drug Houses. These rabbits had been poisoned by diphtheria toxin and it was found that when the fasting blood-sugar was low, insulin failed to lower it, and sometimes even raised it, but when the fasting level was high, insulin always reduced the blood-sugar to a certain extent. On some occasions also normal rabbits with A.B. insulin, one unit, gave a rise of blood-sugar similar to that produced by a small dose of adrenalin. These results obtained with whole insulin (which will shortly be published in extenso) seem to have something common with those of Prof. Funk with his substances A and B. We are advancing as an explanation of these results an abnormal metabolic condition produced by the action of diphtheria toxin on the adrenal and thyroid. We have, however, no adequate explanation to offer for the occasional rise in blood-sugar observed after insulin in normal rabbits.

I am, Sir, yours faithfully,

R. D. LAWRENCE.

Biochemical Department, King's College Hospital,
Nov. 26th, 1926.

THE PROPHYLAXIS OF POLIOMYELITIS.

To the Editor of THE LANCET.

SIR,—In the interesting leading article on poliomyelitis which appeared in your issue of Nov. 27th no reference is made to prophylaxis or treatment with hexamine (urotropine). As our investigations during the last four years on the antiseptic treatment of biliary infections show that very large doses can be administered with perfect safety, it seems advisable to draw attention to the important observations of Flexner and Clark, published in 1911, on the effects of hexamine in preventing the disease in monkeys.

"When a large dose is administered by mouth, its presence can be demonstrated in the cerebro-spinal fluid soon afterwards. We have ascertained that when the virus of poliomyelitis is injected intracerebrally in monkeys, in which the hexamine is already present in the fluid, and the drug is then administered by mouth daily afterwards, in a proportion of animals so treated . . . . the incubation period of the disease is prolonged from 6 to 8 to 24 days, and the onset of paralysis is entirely prevented."

Any attempts to prevent the disease in contacts by similar means in the past have been unlikely to meet with success owing to the relatively small dose which has to be given on account of the irritation of the bladder and hæmaturia which result from the setting free of formalin in acid urine. We have found, however, that so much as 100 gr. of hexamine can be given three times a day so long as alkalis are administered at the same time in sufficient quantity to keep the urine alkaline, as formalin cannot then be set free and the bladder is not irritated. Dr. F. A. Knott has shown that the alkali does not prevent the urotropine acting on the alkaline bile, and in view of Flexner and Clark's observations it seems unlikely that it would inhibit the action in the cerebro-spinal fluid, which is also always alkaline. I would, therefore, suggest giving these large doses to all people who have been in contact with the disease until the incubation period of 14 days has passed, and, perhaps for an additional 14 days because of the possibility that the incubation period would be lengthened by the hexamine as it is in monkeys.

Although Flexner and Clark do not appear to have made any observations as to whether hexamine prevents the full development of the symptom in monkeys when the infection is once established, it has become usual to give the drug during the acute stage of the natural disease. I would suggest that at the first suspicion of the disease being present 100 gr. should be given three times a day instead of he usual 10 or 15 gr.

A mixture containing 60 gr. each of sodium bicarbonate and potassium citrate in 1 oz. of water is given after breakfast, after tea, and after a glass of milk last thing at night. The hexamine is given at the same time, but in a different mixture so that the dose can, if necessary, be varied without altering the dose of alkali. It is, perhaps, safest to begin with 50 gr. in ½ oz. of water and add a drachm of the solution to each dose every day till the full 100 gr. in 1 oz. of water are being given. In the unusual event of bladder irritation occurring the dose of hexamine should be reduced slightly and the dose of alkali further increased.

I am, Sir, yours faithfully,

ARTHUR F. HURST.

New Lodge Clinic, Windsor Forest, Nov. 24th, 1926.

RACIAL DEGENERATION.

To the Editor of THE LANCET

SIR,—I think none who have the interests of the country at heart can have read Dean Inge's lecture on Racial Degeneration, which appeared in THE LANCET on Nov. 27th, without interest, and a sense of the importance and gravity of the indictment, suggested rather than urged, of recent social tendencies.

On the question of general social degeneration medical men, as such, have no special claim to be listened to, but it seems to me on the question of physique the profession has a right, and, indeed, a duty, to make its voice heard, if it has any reason to believe there is even the possibility of widespread deterioration. I believe that if there were a strong and influential medical demand for some sort of official commission of inquiry into the alleged existence of such deterioration and into its causes, if present, we might ultimately get an investigation and a report which would prove of value in checking the mischief.

Personally, I have little doubt, as a result of my experience during the war and since, that deterioration is going on to an alarming extent.

I am, Sir, yours faithfully,

Portsmouth, Nov. 29th, 1926. E. W. DEWEY.

To the Editor of THE LANCET.

SIR,—No doubt every reader of THE LANCET will have enjoyed Dean Inge's eloquent address—the Lloyd Roberts lecture, published on Nov. 27th. No doubt, also, they will regard his pessimistic view of the situation with apprehension, provided they consider that his deductions are based upon an accurate interpretation of existing conditions. That Dean Inge would have spoken with equal pessimism at any period of our history is ever my impression when reading his opinions. Unfortunately, like most other writers upon the welfare of our race, the Dean does not offer any remedies save those which have done duty since social problems first obtruded themselves. The only way out of the difficulty that I have met with is contained in the writings of Mr. Matthias Alexander, whose "Man's Supreme Inheritance" and "Constructive Conscious Control" I would earnestly recommend to Dean Inge as an antidote.

I am, Sir, yours faithfully,

MACLEOD YEARSLEY.

Wimpole-street, W., Nov. 29th, 1926.

THE SUPPLY OF ARTIFICIAL LIMBS.

To the Editor of THE LANCET.

SIR,—The annotation on the Adjustment of Artificial Limbs in your issue of Nov. 20th is very timely, for it is, I think, an undoubted fact that many eminent surgeons perform amputations of the limbs without enough familiarity with the conditions necessary for successful limb-fitting. It is to be hoped that your article will have widespread results in improving the practice of amputation. There is, however, another aspect of the prosthetic problem to which I should like, with your permission, to draw attention.

Early in the course of the Great War it became evident to the authorities concerned in supplying disabled soldiers with artificial limbs that the old War Office system of sending the amputee to the limb-maker and trusting to the latter to supply an appropriate prosthesis was unsatisfactory. The system at present in force under the Ministry of Pensions was therefore substituted, under which limbs are prescribed by surgeons with special experience who also supervise the training in their use and see that the end-results are the best obtainable.

From all that I have heard and observed, I am led to fear that the civilian amputee enjoys none of the advantages which this system gives to his disabled brother. It appears to be a usual practice that as soon as the stump is soundly healed the hospital patient is handed over to the almoner, who gives an order to a surgical instrument-maker who may be only a middleman as far as artificial limbs are concerned. In due course a limb is supplied, and the patient is expected to take it away and use it. Too often he finds that he cannot manage it, and (in the case of the lower limb) he reverts to crutches. Would it not be possible for the hospitals of London to combine to establish a small limb-fitting centre such as those which the Ministry of Pensions has established throughout the country, in which the prescription, fitting, and use of limbs would be carried on under experienced surgical direction?

It may be urged that this work should be undertaken by Queen Mary's Convalescent Auxiliary Hospital at Roehampton. Transport difficulties could no doubt be overcome, but I understand that the work at Roehampton is restricted to a very few firms, while there are other equally excellent limb-makers whose workshops are in London and whom it would be unfair to exclude from their share of hospital custom. I am, Sir, yours faithfully,

Seymour-street, W., Nov. 26th. E. MUIRHEAD LITTLE.

To the Editor of THE LANCET.

SIR,—We wish to correct certain statements in your annotation headed The Adjustment of Artificial Limbs published on Nov. 20th. You state that we fitted the patient with a limb which, despite many modifications, was heavier than it would have been had the stump been a different shape. This is not correct, for the limb we fitted to this patient was our standard light metal limb for below-knee amputation; it is true that we stated that had the stump been longer he would have been more comfortable and able to walk better, but the limb would not have been lighter.

We do not agree that the long stump gives no additional advantage in leverage; we have found from our long experience in fitting limbs that long stumps are better from every point of view. It is easy to understand that with a long stump you have a larger surface upon which to bear the weight of the body, giving more comfort and additional leverage, which gives the patient more walking power and stability. We claim that with a light metal limb we can fit long stumps and still make the artificial limb perfectly symmetrical with its fellow, leaving the artificial limb no heavier than would be the case with a shorter stump. Yours faithfully,

pp. Desoutter Brothers, Limited,

Baker-street, London, W., Nov. 27th. E. R. DESOUTTER.

AN INTERESTING SYNDROME.

To the Editor of THE LANCET.

SIR,—During the last three or four months a number of cases have been referred to me for electrical treatment, either on account of troublesome conditions, such as persistent backache, pains in the thighs and legs, or general debility, which present a remarkable uniformity in history, symptoms, and signs. This uniformity is so definite that I should like to give a brief account of the condition as I have met it and ask your readers whether in their practices they have had similar experiences to mine, and, if they have, whether the syndrome is well known, and, if so, what is the nature of the condition. Consideration of the clinical data at my disposal leads me to be dissatisfied, for many reasons, with the easily made, but indefinite diagnosis, of abdominal influenza.

In all the cases except two (now about 20) the patients have been males. The severity of the symptoms has always been more pronounced in those accustomed to a liberal allowance of alcohol. As regards age, the youngest case seen was a man of about 30 and the oldest one of 55.

History.—There is always a clear account of slowly increasing indefinite malaise, insufficient to disturb the daily work or to make the patient seek advice for one or two weeks. At the termination of this period matters come to a head by one or two nights either of sleeplessness or of greatly disturbed sleep.

The doctor's advice is then sought on account of:—

1. This sleeplessness.
2. Deep-seated pain or great discomfort localised to a small area just above and (usually) slightly to the right of the umbilicus.
3. Painful and excessive flatulence, worse on lying down (accompanied in two or three cases by sudden attacks of retching).
4. Extreme depression. (In two cases with strong alcoholic histories amounting to suicidal tendency.)
5. Distaste for all meats.
6. Discomfort in the muscles of the back and front of thighs, chiefly noticeable as limiting free range of movement, and quite different from the painful calf muscles of influenza.

These six symptoms are the ones referred to above as remarkably constant.

The *physical signs* are nearly equally constant. They are:—

1. Pallor of the skin, which becomes a dirty yellow colour (the patients look ill).
2. Temperature, respiration, and pulse remain normal.
3. The tongue, though not clean, is not strongly furred, but always presents the indentation of the teeth.
4. The abdomen moves well, and can be handled superficially without discomfort, except in the more acute cases; deeper pressure above the umbilicus, however, is always resented over a small area, and is accompanied by much gurgling.
5. Tests made of the sensitivity of the skin of the abdomen by means of a small electrode utilising the induced current, show a strictly localised area of definite but mild hyperalgesia approximately over the deep area of discomfort.
6. Urine, stools, barium meal and test-meal examinations in those cases that had them, yielded no information of value.
7. In the forward lying position the usual range of hyperextension of the thighs on the trunk was much limited and accompanied by a sense of deep abdominal discomfort.

In a number of cases duodenal ulcer and cholecystitis had been suspected, which indicates roughly the clinical status. These cases run a more or less "worrying" course for a week or ten days, then after an interval of a week or more, frequently relapse again and again, but each time less severely. Recovery appears to be slow and incomplete, particularly as regards the flatulence. Electrical measures during the acute stage are, from my experience, definitely contra-indicated; later, combined treatments of diathermy and ultra-violet light help materially to restore energy and abdominal comfort far better than if either of these currents are used separately.

These signs and symptoms do not correspond to any condition within my knowledge, but may be familiar to many of your readers, who could, perhaps, help me with their experience.

I am, Sir, yours faithfully,

London, W., Nov. 29th, 1926. C. B. HEALD.

THE DOG AS TEST OBJECT.

To the Editor of THE LANCET.

SIR,—In the experimental work which led to the isolation of the internal secretion of the pancreas in a form suitable for repeated subcutaneous administration to patients suffering from diabetes mellitus diabetic dogs were used as test objects for extracts made from the degenerated pancreas of the dog. The dog was greatly superior to other animals as a test object because the frequent samples of blood necessary in order to follow the blood-sugar level could be easily obtained by vena puncture by the same painless technique as is used to secure blood samples from patients. Secondly, the pancreas of the dog can be completely removed and a severe diabetes produced. The pancreas of the cat can also be removed, but it is extremely difficult to obtain blood samples from this animal. Blood samples can be easily obtained from the rabbit, but the pancreas is so diffuse that an investigator is never certain if removal has been complete. Thirdly, the signs and symptoms of diabetes in the dog have been more completely recorded than for any other species so that the beneficial effects of an antidiabetic substance could be more easily detected and more accurately estimated in this animal than in any other. It is quite probable that the antidiabetic effect of the first extracts prepared in Toronto would have been missed if a less satisfactory test animal had been used.

Since the dog was the largest laboratory animal in which it had been shown that ligation of the pancreatic ducts was followed by disappearance of the acinous tissue more pancreas was available in this species, in which to seek the elusive antidiabetic substance than in any other. Furthermore, since the most advantageous test animal was the dog it seemed probable that unnecessary difficulties would be encountered if extracts made from the tissue of a foreign species were used.

I am, Sir, yours faithfully,

C. H. BEST.

Department of Physiology, University College, Gower-street, W.C., Nov. 30th, 1926.

*** Dr. Best's letter brings up to date the memorandum issued by the Medical Research Council in 1919 and is dealt with in a leading article.—ED. L.

MEDICINE OR SURGERY FOR THE OCULIST?

To the Editor of THE LANCET.

SIR,—Mr. Ernest Clarke, in his presidential address to the Section of Ophthalmology of the Royal Society of Medicine (THE LANCET, Nov. 20th, p. 1052), has raised a topic of some general interest by his remarks on the advance in the education of the intending oculist. The facts are admirably crystallised in the paragraph:—

"In the early days the only eye work was surgical, and when the various hospitals established eye departments one of the surgeons on the staff was selected as head of that department. Naturally, the younger men who aimed at specialising in eye work concentrated on surgery, and took the Fellowship of the Royal College of Surgeons, the study for which occupied all their time to the exclusion of any deep knowledge of medicine; consequently the proportion of oculists without a special medical degree at this time was 4 *to* 1. As the knowledge of ophthalmology increased it became apparent that medicine was as important, or even more important, than surgery, so that now almost all the younger oculists possess a medical degree and the proportion is reversed."

While everyone will agree with this, the F.R.C.S. remains the indispensable key to hospital appointments, and the waste-paper basket is the receptacle for any application from a Member of the Royal College of Physicians. No doubt the possession of both these diplomas is the ideal, but if one alone is to constitute eligibility, perhaps the "Membership" might be considered more appropriate than the "Fellowship." The much closer relationship of the subject matter of ophthalmology with general medicine than with general surgery is obvious, and it seems unfortunate that Mr. Clarke should have followed up the statement I have quoted above by recalling a paper of seven years past in which it was hinted that "the time might come when some *conscious of not being good at surgery* (my italics) would concentrate on the medical side and call themselves medical ophthalmologists, with the prefix of 'Dr.' which (in London) is not considered to be our correct designation." In the spirit of this remark Mr. Clarke appears to ally himself with the regulations—obsolescent on his own showing—of the hospitals, and, indeed, to impute (which he can hardly wish to do) a motive other than a desire for efficiency to those oculists who have neglected the "Fellowship" for other qualifications.

No one will deny the status of the work done by ophthalmic surgeons in the past, but this has nothing to do with the point; to argue on this would be to confuse *post* and *propter* once more. Nor is the tremendous educational value of the primary examination for the Fellowship in question.

Shorn of irrelevancies, the question is that of "Medicine or Surgery for the Oculist." I do not propose any lowering of standards, but rather a widening of them. The advance is now chiefly in the direction of medicine. Will this be recognised by the equalisation of surgical and medical diplomas? It is to be noted, in passing, that a gynæcologist can be appointed on a medical diploma. I hope that some oculists of experience will think the subject worthy of an expression of their views. I ought to state that I have neither of the diplomas mentioned.

I am, Sir, yours faithfully,

Nov. 22nd, 1926. INCIPIENS.

AN APPEAL.

To the Editor of THE LANCET.

SIR,—A medical man, aged 70, who has no knowledge of this appeal, is sorely pressed. Twenty years ago he was advised on medical grounds to leave his general practice. His health recovered, and for many years he has been able to act as locum tenens, doing work which has kept him alive, but which has prevented him putting by. His wife, who is in indifferent health, does what she can by dressmaking. Of four sons who would now all be helping, three died at the age of 21; one, my friend, in the *Queen Mary* at Jutland; one of cerebro-spinal meningitis at St. Omer; and the other elsewhere abroad. The remaining boy is in the air branch of the Navy, and he sends home the little he can afford.

Recently a prolonged illness, lasting over four months and necessitating several operations, has prevented the doctor from earning a penny, and his financial state is critical. A friend has opened a subscription list with £50; and I, who know the facts, shall be very glad to receive, acknowledge, and forward subscriptions from sympathetic professional colleagues. Perhaps someone may know of an opening for the doctor, preferably in London, on the clerical side of a hospital or its appeal department, or of a medical or other society. He aspires only to a small living wage, and for this he would do first-rate work.—I am, Sir, yours faithfully,

HILDRED CARLILL, M.D. Camb.,
Physician to Westminster Hospital, &c.

146, Harley-street, W., Nov. 29th, 1926.

BULB DERMATITIS.

To the Editor of THE LANCET.

SIR,—In your issue of Nov. 13th you published a paper by me on the occurrence and features of dermatitis from handling flower bulbs. This article attracted the attention of the lay press, and extracts subsequently appeared in several of the daily papers. As a result, numerous requests from all parts of the country have reached me, either directly or through you, asking for details of prevention and cure.

The prevention of the distinctive peri- and hyponychial dermatitis from handling flower bulbs is

comparatively simple. Those exposing themselves to contact with bulbs should trim their nails as closely as comfort will permit. The tips of the fingers should be firmly pressed into a block of good unperfumed soap before starting work. Should irritation under and around the nail supervene in spite of these precautions, a cure may be effected by the use of an ointment consisting of equal quantities of lanoline and castor oil, applied to the affected parts. Gloves or finger-stalls should be worn at work until the cure is completed.—I am, Sir, yours faithfully,

SIBYL G. OVERTON.

Factory Department, Home Office, Whitehall,
Nov. 27th, 1926.

PROTECTIVE INOCULATION AGAINST TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—In his otherwise admirable report of the Tuberculosis Week-end Conference in your issue of Nov. 27th, your reporter has, unfortunately, misunderstood my remarks. What I said was that more than half of those exposed to known sources of tuberculous infection did not appear to suffer from it; so that if protective inoculation were advocated, it would not be easy to decide which persons were in need of it. Infection is, I believe, very frequent in childhood; but the breakdown in health comes usually much later in life, as the result of (mostly) non-tuberculous causes. My opinion is based on the study of over 2000 of my cases. I am, Sir, yours faithfully,

Farnham, Surrey, Nov. 29th, 1926. F. R. WALTERS.

EPIDEMIC ENCEPHALITIS IN DOGS.

To the Editor of THE LANCET.

SIR,—I am much interested in the suggestion made by Dr. C. O. Stallybrass in THE LANCET of Nov. 13th that encephalitis should be regarded rather as a specific disease predisposed to by distemper than as a part of distemper itself. He calls for "epidemiological or bacteriological evidence," if any be available, in favour of the latter view.

Epidemiologically it is impossible to separate distemper from encephalitis of the Sevenoaks type. The better known forms of distemper, such as the bronchisepticus or pulmonary form, as well as the more benign and transitory catarrhal form, are often followed by clonic spasms to which the name "chorea" is usually given by veterinary surgeons. Between this "chorea" and frank encephalitis every grade of nervous involvement and every sort of nervous symptom exist. It is also the case (and this perhaps is more important) that during an epidemic of distemper of the catarrhal type certain cases will be found in which the catarrhal and nervous symptoms appear at the same time. These cases, which are not uncommon, make it very difficult to accept the view that distemper acts merely by predisposing to encephalitis.

It was shown by certain workers for the Distemper Commission [1] that animals guarded by the most stringent precautions from all infections, except deliberately induced distemper, nevertheless developed encephalitis. In these cases the virus did not "breed true," although I am personally inclined to agree with Dr. Stallybrass that it commonly does so—at least within the same epidemic period. But it would not seem necessary that epidemics of encephalitis and influenza (or distemper) should ordinarily coincide, or even "regularly alternate," before we can accept them as no more than occasional phases of the type diseases. Indeed, the fact that they do not fulfil these conditions surely tells with even more force against the contention that the type disease merely predisposes to encephalitis.

I am, Sir, yours faithfully,

Sevenoaks, Nov. 16th, 1926. LESLIE PUGH.

Medical News.

UNIVERSITY OF OXFORD.—On Nov. 27th the degree of Doctor of Medicine was conferred on E. G. T. Liddell (Fellow of Trinity College) and the degree of Bachelor of Medicine on J. de la M. Savage (Wadham College).

Radcliffe Travelling Fellowship.—An examination for a Fellowship of the annual value of £300, and tenable for two years, will begin on Feb. 15th. Candidates must have passed all their examinations for the degree of Bachelor of Arts, and must have passed the last examination for the degree of Bachelor of Medicine not more than four years previously. The period of tenure of the Fellowship has to be devoted to the study of medical science and no Fellow may spend more than nine months in the whole within the United Kingdom. The principal subjects of examination are physiology, pathology, and preventive medicine, and there is a practical examination in pathology. The Fellowship is open to women.

UNIVERSITY OF LONDON.—At the recent examination for the Diploma in Psychological Medicine the following candidates were successful:—

With Special Knowledge of Psychiatry.—Rupert George Anderson, Donald Hugh Cameron, Henry Harris.
With Special Knowledge of Mental Deficiency.—Robert Melvin Macfarlane.

The Paul Philip Reitlinger Prize, offered this year for the best essay embodying the result of some research work on a medical subject carried out by the candidate, has been awarded to William Stewart Duke-Elder, M.A. St. Andrews, who is now working at University College, London, for his essay on the Ocular Circulation: its Normal Pressure Relationships and Their Physiological Significance. The prize, of the value of £30, was founded with funds given to the University by Mr. Albert Reitlinger in memory of his son, a student of Middlesex Hospital Medical School, who died on Dec. 3rd, 1911. Next year the prize will be awarded for the best essay on the Nature of Belief and its Place in Human Experience.

UNIVERSITY OF MANCHESTER.—Dr. William Dyson, Dr. D. S. Sutherland, and Dr. S. R. Wilson have been appointed members of the Board of the Faculty of Medicine.

UNIVERSITY OF GLASGOW.—On Nov. 20th the degree of M.D. was conferred on Evelyn M'Pherson for a thesis on Gastric Analyses in Cases of Diabetes and Glycosuria.

MEDICAL STUDENTS' VISIT TO A SPA.—In connexion with a scheme organised by the International Society of Medical Hydrology nearly 60 medical students and graduates of the University of Bristol visited Bath on Nov. 19th. A lecture-demonstration was given at the Royal Mineral Water Hospital by Dr. Vincent Coates, and visits were made to the various departments for physical treatment.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—On Thursday, Dec. 9th, at 5 P.M., Mr. L. Bathe Rawling will give a special lecture on Injuries to the Head, at the rooms of the Medical Society of London, 11, Chandos-street, W. 1. This will be free to members of the medical profession. On Dec. 6th the Infants Hospital will start a fortnight's course in Diseases of Infants. Attendance will be from 2 P.M. daily and there will be lectures, demonstrations, and two specially arranged visits on the Saturdays and one on a Sunday. The fee will be three guineas. Practical courses in Obstetrics lasting a fortnight or a month can be arranged at the Queen Charlotte's Hospital. Every week the City of London Maternity Hospital holds a course in Obstetrics and Child Welfare, personal application for which must be made to the Fellowship offices. The Fellowship can also arrange clinical assistantships at the Samaritan Hospital. The following courses will be held in January next: A fortnight's intensive course in medicine, surgery, and the specialties at the Prince of Wales's General Hospital from Jan. 10th to 22nd; a fortnight's all-day course in cardiology at the National Hospital for Diseases of the Heart from Jan. 17th to 29th, for which the entries are limited to 20; a fortnight's course in Diseases of Children at the Royal Free Hospital and the Children's Clinic from Jan. 10th to 22nd; and a month's course (Tuesday and Saturday mornings at 11 A.M.) in Psychological Medicine at the Bethlem Royal Hospital from Jan. 11th to Feb. 5th. A further series of lectures on Medical and Surgical Emergencies will be held under the auspices of the Fellowship and there will also be clinical demonstrations in ophthalmology at the Royal Eye Hospital. Copies of all syllabuses of the Special Courses, the Programme of the General Course, and of the *Post-Graduate Medical Journal* may be had from the Secretary of the Fellowship at 1, Wimpole-street, London, W. 1.

Messrs. William Heinemann (Medical Books), Ltd., will shortly publish the fourth edition of Jacobi's "Atlas of Dermochromes," with a new and original text by Dr. Henry MacCormac. The price of the two volumes will be five guineas.

HARVEIAN SOCIETY OF LONDON.—An ordinary meeting of this society will be held at Paddington Town Hall on Thursday, Dec. 9th, at 8.30 P.M., when a discussion on the Ætiology of High Blood Pressure and the Respiratory Phenomena Associated with High Blood Pressure and Chronic Nephritis will be opened by Sir John Broadbent.

INFANT WELFARE AT LLANDUDNO.—On Nov. 26th Mr. Neville Chamberlain, the Minister of Health, opened the War Memorial Infant Welfare and Maternity Centre, the site for which has been given by Lord Mostyn. This is the first building in North Wales to be devoted to the service.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—A meeting will be held at the Miller General Hospital, Greenwich, on Friday, Dec. 10th, at 8.45 P.M., when Dr. Robert Hutchison will deliver the Purvis Oration. His subject will be Prognosis. After the oration there will be a conversazione.

OKEHAMPTON COTTAGE HOSPITAL.—The War Memorial Cottage Hospital, Okehampton, cannot yet be opened owing to the difficulty of obtaining servants. Several advertisements have failed to produce a single answer.

LIGHT DEPARTMENT AT PRESTON INFIRMARY.—On Nov. 25th Dr. Leonard Hill opened the new light department at the Preston and County of Lancaster Queen Victoria Royal Infirmary. In the course of his speech he said that for three years he had pleaded for the introduction of light treatment into schools. Everyone should have an opportunity to take light baths once or twice a week.

IRISH MEDICAL GRADUATES' ASSOCIATION.—The autumn dinner of the Irish Medical Schools and Graduates' Association was held at the Savoy Hotel, London, on Nov. 23rd. Sir William Wheeler, the President, was in the chair, and the guest of honour was Sir Thomas Moloney, lately Lord Chief Justice of Ireland. The toast of "The Guests" was proposed by Sir John Moore and responded to by Sir Thomas Moloney and Lord Shaw of Dunfermline. "The President and Association" was proposed by Dr. R. Travers Smith and Sir William Wheeler responded. Miss Ethel Ashmore, Mr. W. Gardner, "Miss Agnes Treacy" and others contributed to a delightful musical programme.

ROYAL INSTITUTION.—On Thursday, Dec. 9th, at 5.15 P.M., Sir Squire Sprigge, the Editor of THE LANCET, will deliver a lecture at the Royal Institution on Early Medical Literature. On Dec. 16th, at the same hour, he will lecture on Medical Literature in Relation to Journalism. —The Christmas course of juvenile lectures will be delivered by Prof. A. V. Hill. His subject will be Nerves and Muscles: How We Feel and Move, and the course will begin on Tuesday, Dec. 28th, at 3 P.M. The titles of the lectures are: Nerves and the Messages They Carry; Muscles and How They Move (Dec. 30th); the Heart and Some Other Muscles (Jan. 1st); the Lungs and Blood (Jan. 4th); Nerves and Muscles Working Together (Jan. 6th); and Speed, Strength, and Endurance (Jan. 8th). The lectures will be fully illustrated by experiments.

ABERDEEN MEDICO-CHIRURGICAL SOCIETY.—On Nov. 25th the following office-bearers and members of Council were elected: President: Dr. J. F. Christie. Vice-President: Dr. Thomas Fraser. Treasurer: Dr. George Rose. Secretary: Dr. H. Edgar Smith. Editor of Transactions: Mr. G. Herbert Colt. Members of Council: Dr. J. Ross Mackenzie, Mr. W. Anderson, Dr. Peter Howie, Dr. James Crombie, Mr. Andrew Fowler, Mr. Alexander Mitchell, Dr. Henry Peterkin, and Dr. George Williamson. Assistant Secretary: Dr. Robert Richards. Recording Secretary: Mr. A. Fowler.

THE LATE DR. LINTON PALMER.—After a short illness Dr. Charles John Linton Palmer died at Gosport on Nov. 19th. Educated at University College, Liverpool, Dr. Palmer qualified as M.R.C.S. in 1898 and held appointments as resident medical officer at the City Infectious Diseases Hospital, Park Hill, and at the Liverpool Royal Infirmary. He went into practice at Gosport just before the war, and was shortly afterwards appointed civilian medical officer in charge of troops in the district. Later he held a lieutenant's commission in the Royal Army Medical Corps and served on the hospital ships plying in the English Channel. Since the war he had remained in practice at Gosport and was honorary medical officer to the Royal Portsmouth and Gosport Hospital. Dr. Palmer was 55 years of age and leaves a widow and two children.

Sir Thomas Legge has tendered his resignation of the post of Senior Medical Inspector of Factories at the Home Office, finding himself unable to recede from the position which he took up at Geneva in 1921 when he voted for the Draft Convention prohibiting the use of white lead for internal painting of buildings.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—A meeting will be held at 17, Bloomsbury-square, London, W.C., on Dec. 14th at 8 P.M., when a paper will be read on the Vitamins in Their Relation to Pharmacy by Mr. F. H. Carr. After the paper a discussion will be invited. Medical friends of members and student-associates will be welcomed.

"OUR WEEK."—This is the name given to the special effort that is being made this week in celebration of the sixtieth birthday of the Elizabeth Garrett Anderson Hospital. It is hoped, by means of numerous entertainments and functions, to raise a large sum towards the fund for building and rebuilding wards and special departments.

GIFT TO A MEDICAL MAN.—A number of his friends and patients have presented an illuminated album to Dr. Price Morris, of Cadwgan, Old Colwyn, as a record of their appreciation of his medical service to the neighbourhood during almost half a century. Presentations have also been made to his wife and daughter.

GLAMORGANSHIRE HOME FOR THE MENTALLY DEFICIENT.—The Glamorganshire County Council has purchased Hensol Castle from Sir Francis Price Rose as a home for mentally deficient persons. The castle, which was one of the seats of the Earls Talbot before they inherited the Earldom of Shrewsbury, has been sold because the late owner foresees that his successors will not be in a position to maintain it.

THE LATE DR. W. C. W. STAIN.—Dr. William Corbet Stain, whose death at the age of 58 is reported from Audlem, was notable both for his work as a practitioner and his interest in local affairs. Born at Foxton in Leicestershire, he studied medicine at the University of Edinburgh, graduated in 1890, and went to Audlem 32 years ago. Soon acquiring a considerable practice, he became medical officer of health and a justice of the peace. A keen politician, he was also captain of the fire brigade and of the cricket and football clubs, a good shot, and for many years a follower of the South Cheshire and North Staffordshire Hounds. He married in 1915 a daughter of Mr. John Nunnerley, of Hankelow Manor, and she survives him.

CREMATIONS IN MANCHESTER.—At the annual meeting of the Manchester Crematorium, Ltd., on Nov. 25th the following statement by the late Lord Salvesen, of the Edinburgh Court of Session, was quoted to meet a suggestion that cremation might hinder the course of justice: "In my opinion these requirements [the Home Office Regulations] are so stringent as for all practical purposes to exclude the possibility of a body being cremated which has been the victim of foul play." Since the crematorium was opened in 1892 there have been 4622 cremations, and the number has steadily increased during the last five years.

METROPOLITAN ASYLUMS BOARD.—In connexion with the Diploma in Public Health, a three months' course of lectures and demonstrations on Clinical Practice and in Hospital Administration will be given at the North-Eastern Hospital, St. Ann's-road, Tottenham, N., by Dr. F. H. Thomson on Mondays and Wednesdays at 4.45 P.M., and alternate Saturdays at 11 A.M., beginning on Monday, Jan. 3rd. The fee of four guineas should be paid to the clerk to the Board at Victoria Embankment, E.C. 4, before attending the course.

YORKSHIRE ASSOCIATION OF GLASGOW GRADUATES. The annual dinner will be held in the Great Northern Hotel, Leeds, at 6.45 P.M. on Friday, Dec. 17th. The guest of the evening will be Mr. Farquhar Macrae. All old Glasgow graduates resident in Yorkshire are invited to the dinner, particulars of which may be had on application to the honorary secretary, W. MacAdam, M.D., 40, Park-square, Leeds.

THE LATE DR. SILAS HONEYWILL.—Dr. Honeywill, who has died at Bildeston in Suffolk at the age of 72, received his medical education at University College Hospital and qualified as M.R.C.S. Eng. and L.R.C.P. Edin. in 1876. He was for a time ophthalmic assistant at the hospital and settled in Bildeston about 46 years ago as assistant to Dr. J. L. Growse, later taking over the practice himself. At the time of his retirement in 1916 he was medical officer and public vaccinator for one of the districts of the Cosford Union and was well known throughout the district as president of the cricket club, a post which he had held for more than 40 years. Dr. Honeywill leaves a widow and a son.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

SMOKE ABATEMENT BILL.

THE consideration of the Public Health (Smoke Abatement) Bill, which has already passed through the House of Lords, has been completed by Standing Committee B of the House of Commons.

On Nov. 18th, on Clause 1, which provides that a chimney (not being the chimney of a private dwelling-house) sending forth smoke in such quantity as to be a nuisance shall be liable to be dealt with summarily, Mr. H. WILLIAMS moved an amendment restricting the application of the provision to black smoke, and requiring the Ministry of Health to prescribe the standard of the smoke. He said that after all it was impossible to burn fuel without the production of some limited amount of smoke of some kind or another, and if they were going to extend the whole present conception of smoke until it included presumably any kind of vapour which could be seen in any way at all, he thought they would land themselves in great difficulties.

Mr. N. CHAMBERLAIN (Minister of Health) in resisting the amendment, said he justified the provisions of the Bill as they stood by the Report of the Newton Committee. That Committee said that they examined 150 witnesses, who were unanimous that the limitation to black smoke should be removed. It was ridiculous, the right hon. gentleman continued, if they were going to try to limit the injury to the public health caused by the emission of noxious vapour that they should confine the provision to black smoke. It was really impracticable for any central body to prescribe a standard of this kind. The only reasonable way of meeting the difficulties was to give some discretion to the local authority or to the justices in the court.

Lieut.-Colonel FREMANTLE said that the provisions that had been put in the Bill for the protection of industry were considerable. What those who were keen from the point of view of public health in getting some measure of smoke prevention feared was that nothing would be done, just as had been in the case in the past.

The amendment was negatived.

An amendment moved by Lieut.-Colonel ASTBURY to exclude " ash grit and gritty particles " from the expression " smoke " was negatived by 23 votes to 5.

Mr. GREENWOOD moved an amendment debarring the Minister of Health from exempting by Provisional Order " any other industrial process " than the processes mentioned in Clause 1.

The amendment was negatived by 16 votes to 7.

On Nov. 23rd the Committee considered Clause 5, which extends the power to make by-laws to the provision in new buildings, other than private dwelling houses, of heating arrangements to prevent or reduce the emission of smoke.

Captain WATERHOUSE moved an amendment to include private dwelling-houses within the scope of the clause. He said that they were building so many houses nowadays that it seemed a great pity that more stringent provisions were not made to enforce the use of the very best type of grate. In Lord Newton's Report it was stated that 50 per cent. of the smoke nuisance came from private dwelling-houses. At the most under this Bill, as now drafted, they were only seeking to diminish 50 per cent. of the smoke, and he wanted to urge the Minister to diminish part of the other 50 per cent. which came from private dwelling-houses.

Lieut.-Colonel FREMANTLE supported the amendment. He said that to people who had dealt with questions of public health the urgency of this question was obvious, and they said, " For heaven's sake prevent the nuisance being set up in new buildings under new conditions and in new surroundings where possible." Local authorities, especially those who produced electricity and gas, might naturally try to promote experiments in putting up houses without any open fireplaces. He emphatically protested against any such possibility in the name of public health. A great authority at the present time on applied physiology, Dr. Leonard Hill, had recently, and again and again, spoken in regard to the present position of science as regarded heat, ventilation, and heating, and he had shown how in the enclosed systems of heating in which they promoted heat by radiation and convection, they left out entirely the better system of heating from the open fire, and left out the question of ventilation to a large extent. Be that as it might, he did not mind a few experiments being tried if only to show how unsatisfactory they were, and that the people of the country would not have such houses. He thought that it was quite possible by research to evolve a fireplace which could be put into an ordinary working-class house, and which would help to consume the smoke. When that had been proved, it would be an excellent thing to have an amending Bill which would enable the far-sighted local authorities to institute by-laws and to insist that such improved appliances should be applied to all new houses.

Mr. CHAMBERLAIN reminded the Committee that there were 8,000,000 houses existing in the country at present, and not one of these would be touched. All that they would deal with under the amendment were the new houses of the future which were being built at the rate of 200,000 a year. As a matter of fact, they would not even deal with the whole of these houses, because a substantial part of them were being built by local authorities, and there was nothing to prevent them from so constructing their houses that they were fitted with such arrangements as would prevent the emission of smoke.

The amendment was negatived by 18 votes to 7.

On Nov. 24th the Committee amended Clause 9 (which excluded ships from the operation of the Bill), so as to make the Bill apply to ships other than those " habitually used " as sea-going vessels.

A new clause (powers of local authorities to conduct research) was added to the Bill.

The Committee stage was concluded, and the Bill was ordered to be reported to the House.

HOUSE OF LORDS.

THURSDAY, NOV. 25TH.

Lead Paint Poisoning Bill.

ON the motion for the third reading of the Lead Paint (Protection against Poisoning) Bill,

Viscount BERTIE OF THAME moved an amendment exempting from the prohibition provided by the Bill such women as are actually employed in painting at the time of the passing of the Act.

Lord DESBOROUGH, on behalf of the Home Office, accepted the amendment, which was agreed to.

The Bill was read a third time and passed.

Poor-law Bill.

Viscount GAGE, in moving the second reading of the Poor-law Bill, said it was not a measure for the Reform of the Poor-law, but a Bill to consolidate the various enactments relating to the subject of the Poor-law. At present they were to be found in about 100 Acts of Parliament ranging from the Poor Relief Act of Queen Elizabeth's day to modern times. It was proposed to repeal some 60 Acts of Parliament and to repeal in part about 40 others. The general effect of the Bill would be to replace about 220 pages of the Statutes Revised, many of which represented pre-Victorian legislation, and were archaic in form, by an Act of 140 pages couched in modern language and arranged in modern form. In the opinion of the Government it would be impossible satisfactorily to discuss Poor-law Reform by the light of the existing enactments, and that an attempt should be made to reduce the existing Poor-laws to a single code, which would be readily available to all persons interested, and from which the scope and effect of the changes proposed could easily be seen. If the Bill received a second reading, he would propose that it be sent to the Joint Committee on Consolidation Bills.

The Bill was read a second time, and referred to the Join Committee on Consolidation Bills.

HOUSE OF COMMONS.

WEDNESDAY, NOV. 24TH.

Nurses' Hours at West Ham Infirmary.

Miss LAWRENCE asked the Minister of Health the hours per week and the length of shift worked by the nurses and sick attendants at the West Ham central infirmary at the present time, and the hours and shifts worked prior to the establishment of the present appointed board of guardians.—Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) replied: Prior to the appointment of the present Board the hours worked by these officers were 48 a week; they are now 56. Attendants in the observation wards continue to work 48 hours a week. The daily shifts for nurses were 10 hours, and have not been changed; for sick attendants the shifts were eight hours without a break, and are now 10 hours, but under the present system the longest time worked without a break is 4½ hours.

Dog-stealing and Medical Research.

Captain ARTHUR EVANS asked the Home Secretary if his attention had been drawn to the case of a man convicted of stealing dogs for the purpose of selling them to the University College School of Physiology; what action the College authorities took in order to see that stolen animals were not bought; what were the nature of the experiments carried on by this College; and what steps were taken to see that unnecessary cruelty was not practised.

Captain PETER MACDONALD asked the Home Secretary whether his attention had been called to a case of dog-

stealing in London and to the remarks of the magistrate with respect to receiving; whether the police had investigated the procedure under which these animals were collected and disposed of to medical schools; and whether he would consider legislation compelling institutions thus purchasing dogs to keep an inventory of acquisitions, with the prices and names of all vendors, such inventory to be open to police inspection.—Sir W. JOYNSON-HICKS replied: I have seen a press report of the case in question. The College authorities have since stated publicly that their procedure is to buy the animals when required from a general dealer in animals and animals' food, and to require from him a written guarantee that all the animals so purchased were legitimately obtained. The experiments carried on at the College are for the purpose of medical and scientific research and are subject to the conditions and restrictions laid down by the Act 39 and 40 Vic., cap. 77. The laboratory is inspected at frequent intervals by the inspectors appointed under that Act.

Sir ROBERT GOWER asked the Home Secretary whether he would consider the desirability of introducing legislation making it obligatory for persons dealing in dogs, cats, and similar live animals to take out a licence for the purpose and to keep a record of how such animals had been obtained and to whom sold, and providing that these records should be open to regular inspection.—Sir W. JOYNSON-HICKS replied: I do not think that legislation of the kind suggested would be practicable, and I see no reason to doubt that provisions of the ordinary law of larceny are sufficient to deal with thefts of animals.

Sir ROBERT GOWER asked the Home Secretary whether his attention had been called to the comments made on Nov. 20th by Mr. Fry, the stipendiary magistrate at Bow-street police-court, when sentencing Henry William Hewitt, who was, according to the police evidence, employed by the University College Hospital School of Physiology to supply animals for vivisectional experiments and against whom there was a previous conviction for dog-stealing, for stealing and ill-treating certain dogs intended by him for sale to such school; and whether he would consider the desirability of causing an inquiry to be made into the methods by which dogs and other animals were obtained for the purpose of vivisectional experiments in physiological schools.—Sir W. JOYNSON-HICKS replied: Yes, Sir; and I have received a communication from the responsible authorities of the school containing information as to the procedure adopted by them in the purchase of animals, which I understand was not before the magistrate when he dealt with the case. I see in the morning's newspapers that the College has appointed a committee to inquire into the matter. Apart from this case no complaints have reached me, and at present I see no necessity for a general inquiry.

Condition of Casual Wards in Winchester.

Mr. WALTER BAKER asked the Minister of Health whether his attention had been called to the fact that the Winchester Board of Guardians publicly declared their refusal to comply with the requirements of his Inspector to make their casual wards fit for human habitation; whether they had since satisfied the Inspector; and, if not, what steps would be taken.—Sir KINGSLEY WOOD replied: Yes, Sir. My right hon. friend had made further representations to the guardians, and he understands that they have now reconsidered their position and are preparing proposals for the improvement of their wards. The matter will continue to receive his close attention.

Cow Milkers and Disease.

Mr. GROVES asked the Minister of Health whether he would consider the desirability of amending Clause 16 of the Milk and Dairies Order so as to prevent any person engaging in the milking of cows who was suffering from cow-pox, tuberculosis, venereal disease, or skin diseases generally.—Mr. NEVILLE CHAMBERLAIN replied: The prevention of Tuberculosis Regulations, 1925, contain provisions for preventing any person who is suffering from tuberculosis of the respiratory tract from milking cows. I am advised that there is no evidence that the other diseases mentioned are likely to be transmitted to consumers through the medium of milk, and consequently I do not at present propose to modify the Order in the sense suggested.

THURSDAY, NOV. 25TH.

Naval Ratings and Tuberculosis.

Mr. HORE-BELISHA asked the First Lord of the Admiralty the number of men invalided from the Navy with pulmonary tuberculosis during the year 1925; and the number of these whose disease was claimed not to be attributable to the service.—Mr. BRIDGEMAN replied: The number of men invalided from the Royal Navy and Royal Marines with pulmonary tuberculosis during the year 1925 was 189. The number of these whose disease was considered not to be attributable to the Service was 187. It is believed that a certain number of these 187 men claimed disability pensions from the Ministry of Pensions on the ground that the invaliding disability was attributable to War Service. The results of these claims are not known at the Admiralty.

Sir BERTRAM FALLE asked the First Lord of the Admiralty the number of naval ratings borne during the financial year 1913–14; and the number invalided with tuberculosis, also for the financial years 1921–22 and 1924–25.—Mr. DAVIDSON replied: The number of naval ratings and Royal Marines invalided with tuberculosis during the three years in question were 192, 235, and 179 respectively. The average numbers borne were 130,490, 110,823, and 90,527 respectively.

The Factory Bill.

Mr. ROBINSON asked the Home Secretary when it was proposed to take the Second Reading of the Factory Bill.—Sir W. JOYNSON-HICKS replied: The Bill has been withdrawn for this session. As I explained in the Memorandum on the Bill (Cmd. 2716), and also in the course of the debate on March 26th last on the second reading of the Factories Bill introduced by a private member, the Government Bill was introduced in order to give the different industries affected the opportunity during the autumn and winter of examining the proposals, of consulting among themselves with a view to arriving at agreements on disputed points, and of submitting any representations they desire to the Government. It was not proposed to proceed further with the Bill during the present session.

Approved Societies and Dentists' Fees.

Colonel APPLIN asked the Minister of Health whether he was aware that certain approved societies had refused to pay dentists the new regulation fees; and what steps he proposed to take to bring these approved societies into line with the majority.—Mr. NEVILLE CHAMBERLAIN replied: The new scale of fees for dental treatment has not been laid down by regulations, but has been arrived at by agreement between representatives of approved societies and the dental profession. I am aware that a few societies have not yet adopted the scale. I am watching the position, and in the event of its becoming clear that the adoption of the scale by the society is essential to the provision of a satisfactory service for its members, I will take such steps as are necessary to deal with the matter.

Government and Poor-law Reform.

Mr. BENJAMIN SMITH asked the Minister of Health whether it was proposed to lay upon the Table particulars of the Government proposals for the amendment of the Poor-law.—Mr. NEVILLE CHAMBERLAIN replied: No, Sir. A provisional scheme has been published and criticism upon it has been invited from the various bodies interested; the question whether further proposals framed in the light of this criticism shall be made public in the same way is under consideration.

Infantile Paralysis at Uppingham School.

Captain FAIRFAX asked the Minister of Health the extent of the outbreak of infantile paralysis at Uppingham School; and whether any other public school had been attacked by this epidemic.—Mr. NEVILLE CHAMBERLAIN replied: According to the information in the possession of my department, this outbreak was limited to two cases, one of which proved fatal, but a third boy is reported to have developed the disease after his return home. The answer to the last part of the question is, as far as my information goes, in the negative.

MONDAY, NOV. 29TH.

BIRTHS AND DEATHS REGISTRATION BILL.

The Births and Deaths Registration Bill, as amended in Standing Committee, was considered on Report.

Mr. PETO moved the following new clause:—

"The death of any person shall not be registered unless and until there has been delivered to the registrar of the district in which such death has occurred a certificate signed by a medical practitioner of the fact of death and of the cause of death, as respectively in this Act defined, and such certificate shall be given only after the medical practitioner has seen the body."

He said that the Bill provided no machinery for the inspection of a body after death, and there was urgent need of it. There could be no disposal of the body without a registrar's certificate, but that certificate only stated that the registrar had registered the death. It was not worth while just for that to pass the Bill and incur all the public expense which this new machinery would involve. He hoped that the Parliamentary Secretary to the Ministry of Health would give an assurance that his department possessed powers to put an end to the present unsatisfactory state of affairs, and that a very large number of people supposed to be dead should not be in danger of immediate

burial, but that the fact that they were really dead should be certified by a medical man who had seen the body.

Mr. GROVES, in seconding the new clause, said that there was a growing interest in this question. There ought to be actual supervision of the dead and verification by a medical man before interment took place. It was announced by the Registrar-General that only 40 per cent. of the people buried in this country were certified on medical evidence to be actually dead. That was a very unsatisfactory state of affairs. There had been glaring instances where actual funerals had been commenced, in a sense, before death had taken place. He read a letter from an undertaker in Hull who stated that he was called to measure the body of a woman a few weeks ago, who had been laid out, and was said to have been dead for some hours. While at the bedside he noticed a slight movement of the fingers and eyelids, and a doctor was sent for. After his examination, the undertaker was told that his services would not be required. The woman actually died that evening. That was an isolated case, but it proved that there was something in this question. The whole matter was one of expense. The Government could not find the money to do what was required, and medical men would not do it without payment. After all, the panel doctor was responsible for his panel patient until life was extinct, and it ought to be his duty to certify that life was actually extinct after seeing the body. A similar set of circumstances should obtain in Poor-law institutions and hospitals. Where private families had their own doctors there would be no difficulty in the medical man paying an additional visit after death. The new clause gave the Government an opportunity to make the necessary representations to the British Medical Council seriously to consider the matter and to see if this long-standing grievance could not be brought to an end.

Lieut.-Colonel FREMANTLE said that this amendment was an alternative to that which he had put down, which was originally a specific clause in the Bill with which he was personally associated. In the Bills he had introduced in previous years on this subject, his aim had been to meet the particular objections put forward by Mr. Peto. He wished to satisfy those who feared that there was a danger of being buried alive, and he went into the matter very thoroughly and intimately with those concerned to see what could be done. The stage which Mr. Peto and his friends had reached was one he (Lieut.-Colonel Fremantle) had passed through with many others, but his hon. friends had not gone so deeply into the details. This matter was not merely one of expense; the real question was that it was impracticable from the point of view of the doctor's time. That argument really met what appeared, at first sight, to be the appalling statement that only 40 per cent. of deaths were certified after a personal view of the body by the doctor. If they referred to the experience of their own lives they could understand that if the doctor was visiting a patient regularly, over and over again, and the patient was gradually going downhill, the doctor could not be there, and had no cause to be there, every minute right up to the very last. The doctor saw the end coming, and he naturally discreetly retired. He would call in the course of his round, and he retired when there could be no question about the end in any case. Of the 60 per cent. of deaths certified without actual view of the body, they might take it that in practically every one of them the doctor was quite assured in his own mind, when he signed the certificate, that death had supervened, and was bound to do so. There might be a case of error here and there, but they should look at the doctor's practice. In ordinary practice, the doctor was busy on his round from the time he had finished his morning surgery until the evening. He had often no time for his meals, which as a rule were scratch meals. His was a "scratch" life, and every now and then he took what he could in the way of an hour off, which he enjoyed thoroughly. Members of the Labour Party were constantly raising the question of panel doctors having too many patients on their panel, while others were not sufficiently occupied. He admitted that the proposal would give greater confidence to the public, but it was impracticable for the simple reason that there were only a certain number of doctors in this country and, in a very large number of areas, they were occupied for practically the whole of their time. If this extra duty were thrown on the doctors, they would undertake it, but it would be at the expense of their other patients. It was a question of proportion. The only way to meet the case was that suggested in an amendment of which he had given notice. That amendment suggested that after consultation with the Government department, a special officer might be appointed for this special purpose. His amendment proposed that the county boroughs might, where they wished, appoint a special officer, and no doubt some of the boroughs—the L.C.C. would have done so—would have appointed a man who would have helped materially in the worst cases. That would have been a trial experiment of incalculable value, and he was very sorry that the Society that had this fear of premature burial did not accept this half-measure, but went out for the whole proposal in Mr. Peto's amendment. As so often happened, in aiming at the impracticable the Society had lost the half loaf which he had offered.

Dr. VERNON DAVIES said that he had not the slightest hesitation in saying that so far as the towns were concerned and the districts near towns, the proposal that the doctor should see the body after death was perfectly feasible. In 23 years' practice he had only failed once to see a patient after death. In the case of the country districts the matter was not so easy, as a doctor might have to come 20 miles to see a body. If something could be done to meet the case of the country areas he would be prepared to support the proposal.

Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) said that under the Act of 1874 a doctor in attendance on a deceased person in his last illness was required to give a certificate as to the cause of death to the best of his knowledge and belief. If there was no medical certificate, the registrar referred the question at once to the coroner, and if the death was due to an accident, an industrial disease, or other cause which was appropriate for consideration by the coroner, the registrar referred it to the coroner for registration. The certificate was thus even under present circumstances an important element in the evidence determining how the case was to be treated. A doctor was not required to see the deceased person after death, nor was it essential for the purposes of a certificate that he should do so. In ordinary cases where he had attended the deceased until shortly before death, and was informed by a relative that death had taken place, that knowledge would enable him to certify the cause of death, provided the cause of death was consistent with the opinion he had formed of the disease which was the cause of death. Hon. Members had urged that an inspection of the body should take place in every case by a medical man before a certificate was given. It would be a great pity to imperil the very useful provisions of this Bill, which had been supported by all parties, because of a question of this kind, and under those circumstances they had considered what steps could be taken to meet the views of his hon. friends and others who felt strongly on this matter. It was true that in about 40 per cent. of cases the doctors did see the deceased after death, but the difficulty of meeting the situation was very largely experienced in the rural areas. It was very difficult to impose not only on medical men but on the families of the deceased persons charges and expenses which in many cases they would resent. Therefore he suggested that the case might be met by the Registrar-General's office extending the system of the reference by registrars to coroners on the facts as disclosed by the medical certificate of the cause of death. If that policy was pursued, as they intended that it should be, the certificate would show whether the doctor had seen the deceased after death, and how long before death he last saw him alive; and it would thus be possible to see that any case not seen after death, or a reasonably short period before death, would come under review by the coroner before registration or burial. It was to be anticipated that this arrangement in addition to bringing a large class of the more doubtful cases under special review, would greatly increase the proportion of cases seen by a doctor after death, and the improvement in that respect would be progressive to the extent of reaching by stages a standard which even Mr. Peto might regard as satisfactory. In order that the progress and success of this course of action might be properly watched, the Registrar-General would obtain statistics showing the proportion of deaths certified by doctors who had seen the deceased after death, and he (Sir K. Wood) would undertake that these figures should be published in the Registrar-General's annual publication. The Minister of Health was also prepared to say that if the result of the action now proposed was ineffective, he would be prepared to reconsider the whole question with a view to securing the object which they had in common by other means, either by executive or legislative action.

Mr. PETO withdrew his new clause.

The Report stage of the Bill was completed.

Sir KINGSLEY WOOD moved an amendment to provide that the Bill should come into operation on July 1st instead of Jan. 1st. He said that this was necessary in order to allow certain arrangements to be made.

The amendment was agreed to.

On the motion that the Bill be read a third time,

Mr. GROVES, in supporting the Third Reading, repeated his plea that panel doctors should view the body before certification.

Lieut.-Colonel FREMANTLE thanked the Ministry of Health and the House for supporting the Bill. He said that the feature of it which would be found most useful would be the notification of still-births.

The Bill was read a third time.

MENTAL DEFICIENCY BILL.

Mr. NEVILLE CHAMBERLAIN, Minister of Health, in moving the second reading of the Mental Deficiency Bill (which has already passed through the House of Lords), said that it was a measure which was urgently required in the interests of mental defectives themselves. The real substance of the Bill was to be found in the first clause which extended the definition of defectives. Hitherto they had found themselves limited and to some extent cramped in dealing with mental defective cases which were not defective from birth or early age. There had been some extremely painful and distressing cases of encephalitis lethargica in which most serious changes had taken place, but as the boy or girl was not of an early age, he or she could not be dealt with under the existing law. The Bill had been altered so that cases could be dealt with in which the mental deficiency was due to disease, injury, or other causes. Although the existing Act authorised combination of local authorities, it did not enable the local authority to provide additional beds which could be lent to other authorities, but Clause 6 of this Bill provided for such procedure and enabled the local mental deficiency authority, and the local education authority who had responsibility for certain classes of defectives of school age, to provide an institution jointly. He hoped that mutual arrangements would be come to whereby the best use would be made of the provisions of this Bill, which had the unqualified support of the Central Association for Mental Welfare, which comprised 50 voluntary associations throughout the country. The measure did not interfere in any way with the safeguards in the Mental Deficiency Act. They all recognised the strong public anxiety that people should not be treated as mental defectives without sufficient cause. A mental defective might only be dealt with by Order if in addition to being a mental defective he was found "neglected, abandoned, or without visible means of support, or cruelly treated; if he is found guilty of some criminal offence, or if he is undergoing imprisonment, or is an habitual drunkard within the meaning of the Inebriates Act; if he is notified by the local education authority as a mental defective needing care and control; or in the case of a woman, if she is in receipt of poor relief at the time of giving birth to an illegitimate child." In addition to these general limitations, there were the following further safeguards. There must be two medical certificates, one of which must be signed by a medical practitioner specially approved for the purpose, and the case then came before a judicial authority. The judicial authority must be satisfied that the person was a defective and that he was a subject to be dealt with under the Act for one or other of the reasons mentioned above; and then the judicial authority was only empowered to make an Order if he thought it desirable to do so in the interests of the defective. All these safeguards applied before the case was sent to an institution for care and treatment. At the end of a year special medical and other reports had to be made on each case and forwarded to the Board of Control. If the Board, after considering these reports and the means of care and supervision which would be available if the defective were discharged, came to the conclusion that the continuance of the Order was required in the defective's interest, they might order continued detention in the institution for a further year. The same procedure was followed at the end of succeeding periods of five years each. In the case of a defective under the age of 21 there was the further safeguard—namely, that the visitors might, when the case arrived at the age of 21, discharge the defective if they thought that his detention was no longer required in his own interest. All defectives detained under the Mental Deficiency Act were visited by members of the Board of Control from time to time. If at any time the Board felt that any particular defective could with advantage to himself and without danger to the public be discharged, they had power to discharge him. As the existing safeguards were not diminished, he put it to the House that ample safeguards were already provided to see that no injustice or miscarriage of the beneficent provisions of this Bill should take place.

Mr. RHYS DAVIES moved the rejection of the Bill. He said that no one on the Opposition side of the House wished to prevent the Minister of Health from dealing with the consequences of that terrible disease, sleepy sickness. When, however, this Bill was introduced in the House of Lords, the only substantial reason given by the mover was that the Ministry of Health had consulted some medical experts on the subject of widening the scope of the Act of 1913. The question was much too big to be settled by medical experts alone. Up to 1913, as he understood, the doors of mental institutions were as wide open as the Minister of Health now wished to make them for placing people in these institutions, but because of an agitation throughout the country against putting people away in such institutions who ought never to be there, an Act was passed limiting the number of cases, and specifying what type of case was to be dealt with. The Minister by this Bill was going to destroy practically all the main provisions of the Act of 1913. This Bill was not confined to children; it opened the door so that anyone of any age might be dealt with. Having studied the Report of the Royal Commission on Lunacy, he could see no indication in the recommendations with regard to this point. Surely, if the Royal Commission had thought that an amendment of the law on these lines was desirable, they would have made a recommendation on the matter. Again, a committee had recently submitted a report on the question of sexual offences against young persons. In that report, however, there was a definite recommendation that this change should be made. Another committee on Juvenile Offences was still deliberating, and he thought that it was very unwise to bring in a Bill of this kind before the reports of all these committees had been considered by the Government.

Mr. R. MORRISON seconded the motion for rejection.

Commander WILLIAMS said that if the Bill was to have a second reading the House ought to have some sort of explanation as to how far it was intended to carry it, and whether the burdens were going to be mainly on the taxpayer or on the ratepayer. Was it likely to mean an enlargement of the present institutions and staff? If they had not sufficient staff and sufficient institutions, it was not very useful to try to enlarge the number of people they were going to take in.

Mr. AMMON said that he was a little concerned about the classification of encephalitis lethargica cases, which were not what were known medically as mental defectives. Magistrates and judges who had had cases of this kind before them had deplored the fact that they had either to make criminals of the persons charged or to send them to asylums as mental defectives. Some accommodation should be provided for such cases. Under this Bill there was no guarantee that any special care would be given to these people.

Sir KINGSLEY WOOD said that taking the cases throughout the country there was not sufficient accommodation at present, but this Bill would enable the accommodation which at present existed to be more usefully employed. Mr. Rhys Davies was not quite correct when he said that they were destroying the main provisions of the Act of 1913, because prior to that Act there was no power in this country to deal with mental defectives at all. It was quite true that in certain respects they were opening the door by this Bill, and it was very necessary that the door should be opened. In their latest report the Board of Control, after referring to the number of cases which had unhappily arisen in this connexion, said: "There are certain legal difficulties of bringing some defectives of this class under the Mental Deficiency Act, though they are clearly in need of the care and control for their protection which would be provided under that Act." They needed more of the hospital spirit in the treatment of these unfortunate people, and under this Bill the treatment was firstly, supervision, secondly, guardianship, and thirdly, institutional care. The definition in the Bill had been very carefully settled by many eminent medical men whom they had called into consultation, with a view to arriving at something that would meet all classes of cases which ought to be treated. No financial resolution was required for this Bill; therefore, as far as the taxes were concerned, they were not making any further demand on the community. But the measure might very well call for further assistance from the rates. In the long run, whatever might be the immediate expense, it would be better both for the rates and the taxes that this Bill should be passed.

Sir H. SLESSER said that the Bill introduced an entirely new class of persons into the category of mental defectives. Before 1913 there was no such creature known to the law as a mental defective; then, after great discussion the definition of the 1913 Act was set up, and the description was limited to persons who were mentally defective from birth or an early age. Now they had an entirely new proposition, which was that the term should include anybody of any age who happened by injury, disease, or other cause to become what a doctor considered to be a mental defective, and what a magistrate or a court was prepared to certify as such under the terms of the measure.

Mr. CHAMBERLAIN said that he thought that the hon. and learned Member was under a misapprehension. The words used were "development of mind," and development of mind only took place before adult age, and therefore the definition was really limited.

Sir H. SLESSER said he could not accept that view. The Bill dealt with every "disease, injury, or other cause," and who knew where this thing would end? He wanted to be sure that at any rate someone had made a protest that this was a dangerous course on which they were embarking on insufficient information.

Dr. VERNON DAVIES said he was not sure whether he understood the Minister when he referred to the case of encephalitis lethargica to refer to elderly people. The Bill referred to a condition of arrested or incomplete development of mind. A man of 50 who got encephalitis lethargica

and developed some of these awful symptoms afterwards was not necessarily suffering from arrested or incomplete development. It was a perverted development, and the great benefit of this Bill was that it enabled them to take charge of these sad cases. It was just as important that a man of 60 or 70 years of age should be under control after this disease as a child of 9 or 10. He would like to be quite certain whether people of all ages could be included under the Bill. He should also like, before the Committee stage, to see if they could not introduce the words " or perverted " into the definition of mental defectives, because arrested or incomplete development was not sufficient.

Captain W. BENN asked the Minister of Health whether the Bill applied only to adolescents or to persons of all ages.

Mr. CHAMBERLAIN said that Dr. Davies had confirmed his view that the Bill as it stood did not deal with people suffering from perverted development. He took it that the hon. Member thought it might arise where a person had arrived at a later age. That was a point which must be considered in Committee. As far as his own view was concerned, clearly it was impossible at present to deal with all ages; it was only possible to deal with those mental defectives whose development had been arrested, or rendered incomplete by one of the causes specified.

Lieut.-Colonel FREMANTLE said he had had the privilege of serving on committees with the experts who drew up the definition, or something like it, and submitted it to the Ministry of Health. It was quite clear in their mind that they wished only to extend the definition to adolescents, and not to extend it to later ages. They did not consider these cases sufficiently numerous to require the definition to extend to them. But even the most learned experts of the medical profession were liable to err in their definitions.

Mr. RHYS DAVIES withdrew his motion for rejection.

The Bill was read a second time and committed to a Standing Committee.

Milk Regulations and Imported Milk.

Brigadier-General CLIFTON BROWN asked the Minister of Health whether milk produced in Ireland, the Channel Islands, and the Isle of Man would come under the Public Health (Imported Milk) Regulations, 1926, or under the Milk and Dairies Order, 1926, for England; and, if it came under the latter, what steps were to be taken to see that the Order was carried out in the above-named countries.—Sir KINGSLEY WOOD replied: Milk brought from Ireland, the Channel Islands, and the Isle of Man will not come under either the Public Health (Imported Milk) Regulations or the Milk and Dairies Order.

TUESDAY, NOV. 30TH.

Smoke Nuisance at Palace of Westminster.

Mr. BENJAMIN SMITH asked the Under Secretary of State for the Home Department, as representing the First Commissioner of Works, whether his attention had been called to the volumes of black smoke issuing from the smoke-stack of the Palace of Westminster between the hours of 10 and 11 A.M.; whether any complaints had been received from St. Thomas's Hospital; and whether any summons from the local authority had been received for the abatement of the nuisance caused.—Captain HACKING replied: As regards the first part of the question, the attention of my right hon. friend has been called to this nuisance, which is due to the use of foreign coal, and it is hoped that an improvement will be effected when we are able to revert to the use of Welsh coal. The answer to the second and third parts of the question is in the negative.

Ventilation Experiment in Postal Tube.

Mr. THURTLE asked the Secretary of State for War if he could make a statement as to the object of the recent action of his department in sending a company of soldiers into the London postal tube and keeping them there for a number of hours.—Sir L. WORTHINGTON-EVANS replied: The experiment was designed to furnish data regarding the ventilation required under certain conditions in underground shelters, such as dug-outs.

THE LATE DR. J. H. REYNOLDS.—Dr. Joseph Henry Reynolds, who died on Nov. 12th, had worked in Fulham for nearly a quarter of a century and had built up a large practice in the district. He was a son of the late Mr. James Reynolds and was born in 1870 at Gloucester, where he was educated at the Crypt Grammar School. He went to London as a student at the Middlesex Hospital and graduated M.B., C.M. in the University of Edinburgh in 1896. He then held a series of house appointments at the Edinburgh Royal Infirmary and at the Miller Hospital, Greenwich, later becoming assistant medical superintendent at the Brentford Union Infirmary. At his death Dr. Reynolds was 56 years of age. He married a daughter of the late Lieut.-Colonel R. A. V. Pope, and she survives him.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY, Dec. 7th.—8.30 P.M., PATHOLOGY. Laboratory Meeting in the Inoculation Department, St. Mary's Hospital, Paddington, W. Communications, &c.: Sir Almroth Wright: New Technique for Measuring the Bactericidal Power of Blood. V. D. Allison and A. Fleming: Some Experiments on Lysozyme. E. W. Todd: Observations on the Virulence of Hæmolytic Streptococci. J. Freeman and D. M. E. Thomas: Reaction of the Guinea-Pig Uterus to Pollen. A. Fleming and I. Maclean: Toxic Granules in Leucocytes. W. Newcome: Recent Pathological Specimens. 8.30 P.M. ORTHOPÆDICS. Discussion: The Treatment and Results of Fracture of the Upper End of the Femur in Adults (excluding the shaft). Mr. S. L. Higgs will read the opening paper. Other speakers: Prof. Noordenbos (of Amsterdam), Sir Charters Symonds, Mr. T. H. Openshaw, Mr. Hey Groves, Mr. R. C. Elmslie, Mr. Magnus Redding, Mr. E. M. Cowell, Mr. Rowley Bristow, Mr. H. A. T. Fairbank, Mr. A. H. Todd.

THURSDAY.—8.30 P.M., NEUROLOGY. Mr. Macdonald Critchley: Mirror Writing and its Significance. STUDY OF DISEASE IN CHILDREN AND PSYCHIATRY: Members of these Sections are invited to attend this meeting and take part in the discussion.

FRIDAY.—5.30 P.M., CLINICAL. (Cases at 5 P.M.) Cases: Mr. P. Turner: A Case of Old Osteomyelitis of Astragalus. Dr. Worster-Drought: Two Cases of Serratus Magnus Paralysis. Mr. A. E. Mortimer Woolf: (1) Lymphangioma of Tongue; (2) Hæmangioma of Tongue. Dr. L. S. T. Burrell: A Case of Acrocyanosis. Mr. E. Pearce Gould: Sebaceous Horn of the Cheek. Dr. Bedford: Two Cases of Aneurysmal Dilatation of Left Auricle (with mitral stenosis). Mr. W. H. Ogilvie: A Case of Infantile Paralysis with Sexual Precocity. Dr. Parkes Weber (with Dr. Gunewardene): Lipodystrophia Progressiva, with Face only Affected. Mr. L. R. Broster: Ulcer of the Hand for Diagnosis. 5 P.M., OPHTHALMOLOGY. Clinical Meeting at the Central London Ophthalmic Hospital.

BIOCHEMICAL SOCIETY.

MONDAY, Dec. 6th.—5 P.M. (in the Biochemical Laboratory, Imperial College of Science and Technology, South Kensington). Communications: Dr. Krestin and J. R. Marrack: The Calcium in Body Fluids in Nephritis. D. Jordan Lloyd: The Mutual Influence of pH and Salt Concentration on Protein Swelling. C. R. Harington and G. Barger: Chemistry of Thyroxin. III. Constitution and Synthesis of Thyroxin. H. W. Buston and S. B. Schryver: The Basic Hydrolysis Products of Gelatine. I. M. Heilbron, E. D. Kamm, and R. A. Morton: Absorption Spectra of Cholesterol and its Possible Biological Significance with Reference to Vitamin D. O. Rosenheim and T. A. Webster: Further Observations on the Photochemical Formation of Vitamin D. A Demonstration of Methods Employed for Purifying and Investigating the Proteins (Electro-dialysis, &c.) will be given.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.

THURSDAY, Dec. 9th.—8.15 P.M., preceded at 7.45 P.M. by a demonstration on Some Tropical Liver Infections. Dr. H. S. Stannus: Tropical Neurasthenia.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Dec. 6th, to SATURDAY, Dec. 11th.—FELLOWSHIP OF MEDICINE. Special Lecture at the Medical Society, 11, Chandos-street, W. Thurs., Dec. 9th, at 5 P.M., Mr. L. Bathe Rawling: On Injuries of the Head. Free to all members of the medical profession.—INFANTS HOSPITAL, Vincent-square, S.W. Special course on Diseases of Infants. Every afternoon from 2 P.M. Special Lectures and Demonstrations. Sat., Visit to the model pasteurising plant, Willesden.—ST. JOHN'S HOSPITAL, Leicester-square, W.C. Last week of Special Course in Dermatology.—WEST END HOSPITAL FOR NERVOUS DISEASES, Welbeck-street, W. Last fortnight of Special Course of Lecture-Demonstrations upon selected neurological cases. Every afternoon at 5 P.M. Further information from the Secretary.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, Dec. 6th.—10 A.M., Surgical Clinic. 2 P.M., Medical Cases in the Wards. 2.30 P.M. to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 P.M. to 5 P.M., Medical, Surgical, Throat, Nose, and Ear Clinics. Operations.

WEDNESDAY.—2.30 P.M. to 5 P.M., Medical Skin and Eye Clinics. Operations.

THURSDAY.—11.30 A.M., Dental Clinic. 2.30 P.M. to 5 P.M., Medical, Surgical, and Ear, Nose, and Throat Clinics. Operations.

FRIDAY.—10.30 A.M., Throat, Nose, and Ear Clinics. 2.30 P.M. to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.

On Thursday, Dec. 9th, at 2.30 P.M., there will be a special demonstration of Surgical Cases by Mr. W. C. Tanner.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, Dec. 6th.—10 A.M., Mr. MacDonald: Genito-Urinary Operations. 12 noon, Mr. Simmonds: Fractures and Applied Anatomy. 2 P.M., Mr. Donald Armour: Operations.

TUESDAY.—10 A.M., Medical Registrar: Clinical Methods. 12 noon, Dr. Burrell: Chest Cases. 2 P.M., Mr. Sinclair: Surgical Out-patients.

WEDNESDAY.—12.15 P.M., Dr. Burnford: Medical Pathology. 2 P.M., Mr. Tyrrell Gray: Operations. 2 P.M., Dr. Owen: Medical Out-patients.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Department. 2 P.M., Mr. Bishop Harman: Eye Department. 3 P.M., Sir Henry Simson: Gynæcological Wards.

FRIDAY.—10.30 A.M., Dr. Dowling: Skin Dept. 11 A.M., Dr. Pritchard: Modern Methods in Medicine. 2 P.M., Mr. Vlasto: Throat, Nose and Ear Dept.

SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.

Daily, 10 A.M. to 5 P.M., Operations, Medical, Surgical, and Special Out-patient Departments, Saturdays, 10 A.M. to 1 P.M.

POST-GRADUATE HOSTEL, Imperial Hotel, Russell-square, W.C.

TUESDAY, Dec. 7th.—9 P.M., Mr. A. C. Morson: Peccant Prostate.

THURSDAY.—9 P.M., Sir Charters Symonds: Carcinoma Œsophagus.

FRIDAY.—9 P.M., Mr. T. H. A. Chaplin: Medical Service at Sea in the Mercantile Marine.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street.

THURSDAY, Dec. 9th.—4 P.M., Mr. O. L. Addison: Cleft Palate.

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL, Gray's Inn-road, W.C.

FRIDAY, Dec. 10th.—4 P.M. Mr. Nicol Rankin: Earache.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.

TUESDAY, Dec. 7th.—5 P.M., Dr. W. Griffith: Eczema (1).

THURSDAY.—5 P.M., Dr. W. Griffith: Eczema (2).

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.

TUESDAY, Dec. 7th.—4.15 P.M., Dr. J. Shaw Dunn: Some Points Respecting Mineral Metabolism.

FRIDAY.—4.15 P.M., Dr. F. E. Tylecote: Syphilis of the Lungs.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.

FRIDAY, Dec. 10th.—3.30 P.M., at the Royal Infirmary: Dr. Barnes: Medical Clinical Cases.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.

WEDNESDAY, Dec. 8th.—4 P.M., Lieut.-Colonel F. E. Fremantle: The Rôle of Parliament in Regard to Health Legislation.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, St. Andrews.

TUESDAY, Dec. 7th.—4 P.M., Prof. G. Lovell Gulland: High Blood Pressure, Albuminuria and Glycosuria in their Relation to Life Insurance. Discussion to be opened by Dr MacTier.

Appointments.

DUNCOMBE, C., M.B., B.Ch. Camb., D.P.H. Oxf., has been appointed Assistant Medical Officer of Health for Doncaster and Schools Medical Officer.

FAIRER, J. A., M.B., Ch.B. Manch., D.P.H., Medical Officer of Health for Leicestershire.

TAYLOR, J. S., M.B., Ch.B. Aberd., Assistant Medical Officer of Health for Manchester.

Certifying Surgeon under the Factory and Workshop Acts: WHITBY, R. B., M.B., Ch.B. Brist. (Mere District of Wiltshire); WATT, J. C. (Tunbridge Wells); MCENTEE, E. F., M.B., Ch.B. Belf. (Castleton District of the County of Derby).

Vacancies.

For further information refer to the advertisement columns.

Acton Hospital, Gunnersbury-lane, Acton, W.—Res. M.O. £150.

All Saints' Hospital for Genito-Urinary Diseases, Vauxhall Bridge-road, S.W.—Res. Sen. H.S. Also Hon. Res. Jun. H.S. At rate of £200 and £100 respectively.

Ashton-under-Lyne District Infirmary.—H.S. At rate of £150.

Birkenhead Borough Hospital.—Cas. H.S. £100.

Birmingham and Midland Eye Hospital.—Two H.S.'s. £120 and £110 respectively.

Blackpool, Victoria Hospital.—Asst. H.S. £120.

Bridgwater General Hospital.—H.S. £130.

Brighton, Borough Infectious Disease Hospital and Sanatorium. Res. M.O. £350.

Brighton, Royal Alexandra Hospital for Sick Children.—H.S. At rate of £100.

Brighton, Sussex, Maternity and Women's Hospital.—Second Hon. Obstet. Phys.

Cairo University.—Prof. of Pathology, £E.2000. Also Prof. of Bacteriology £E.1500.

Cancer Hospital, Fulham-road, S.W.—Pathologist. £1000.

Canterbury City and Borough, &c.—M.O.H. and School M.O. £800.

Cardiff City, Mental Hospital, Whitchurch.—Res. Clin. Asst. 50 guineas for six months.

Chester Royal Infirmary.—Second and Third H.S.'s. Each £150.

City of London Hospital for Diseases of Heart and Lungs, Victoria Park, E.—Res. M.O. £250. H.P. At rate of £100. M.O. to Out-patient Dept. At rate of £150.

Dreadnought Hospital, Greenwich.—H.P. and H.S. Each at rate of £110.

East African Medical Service.—Two Asst. Bacteriologists. £600.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—H.S. At rate of £125. Also Part-time Pathologist. £400.

Hampshire County Council.—Dental S. £500.

Hospital for Sick Children, Great Ormond-street, W.C.—Surg., Phys. to Out-patients. Anæsthetist. £15 15*s.*

Liverpool, St. Paul's Eye Hospital, Oldhall-street.—H.S. At rate of £60.

London Hospital, E.—First Asst. and Reg. to one of the five Surgical Firms. £300.

London Lock Hospital, 91, Dean-street, W.—Clin. Assts. to Out-patients.

Macclesfield, Cheshire County Mental Hospital, Parkside.—Asst. M.O. £350.

Maidstone, Kent County Ophthalmic Hospital.—Hon. Ophth. S.

Manchester, Ancoats Hospital.—H.S. At rate of £100.

Manchester Royal Infirmary.—Asst. Reg. Surg. O. At rate of £150.

Manchester, St. Mary's Hospital.—Hon. Asst. S.

Middlesex Hospital and Medical School.—Surg. Registrar and Med. Registrar. Each £300.

Miller General Hospital for South-East London, Greenwich-road, S.E.—Res. Cas. O. £150. Also H.S. £125.

Norwich, Norfolk and Norwich Hospital.—H.P. and H.S. Each £120.

Nottingham City Laboratory.—Pathologist. £750.

Nottinghamshire County Council, &c.—Asst. Sch. M.O. and Dist. M.O.H. £700.

Plymouth, South Devon and East Cornwall Hospital.—Jun. H.S.

Queen Charlotte's Maternity Hospital, Marylebone-road, N.W.—Asst. Res. M.O. At rate of £80.

Royal Army Medical Corps.—Commissions.

Royal Free Hospital, Gray's Inn-road, W.C.—Orthopædic Surg.

Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—H.P. At rate of £100.

Ruthin Castle, North Wales.—Jun. P. At rate of £200.

Ryde, Royal Isle of Wight County Hospital.—Vacancy on Hon. Med. Staff.

Salford Royal Hospital.—Res. Surg. O. £200. Two H.S.'s, H.P., and Cas. H.S. Each at rate of £125.

Swansea General and Eye Hospital, Beck Laboratory.—Asst. Pathologist. £500.

Wallasey, Victoria Central Hospital.—Jun. H.S. £100.

West Bromwich County Borough.—M.O.H. £1000.

West London Hospital, Hammersmith, W.—Phys. Also H.S., H.P., Res. Asst. Cas. O., and Aural and Ophth. H.S. Each at rate of £100.

Winchester, Royal Hampshire County Hospital.—H.P. At rate of £150.

Wolverhampton and Staffordshire Hospital.—Res. M. O. At rate of £150.

Wrexham and East Denbighshire War Memorial Hospital.—Two Res. H.S.'s. Each at rate of £100.

The Chief Inspector of Factories announces a vacant appointment for a Certifying Factory Surgeon at Crediton (Devon).

Births, Marriages, and Deaths.

BIRTHS.

BURRELL.—On Nov. 21st, at "Dunley," Knutsford, the wife of Dr. E. M. Burrell, of a daughter.

BUXTON.—On Nov. 24th, at Queen Anne-street, W., the wife of St. J. D. Buxton, F.R.C.S., of a daughter.

MARRIAGES.

FREW—MORTON.—On Nov. 25th, at the Presbyterian Church, Putney, John Frew, M.B., D.P.H., to Katharine Matheson, eldest daughter of Dr. and Mrs. John Morton, Gwendolen-avenue, Putney.

DEATHS.

BUTCHER.—On Nov. 25th, suddenly, at "Grangefield," Park-road South, Birkenhead, Arthur Herbert Butcher, M.R.C.S., L.R.C.P.

PENNY.—On Nov. 27th, at Querns Cottage, Swanage, Edward Penny, M.D., late of Marlborough.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

LONDON POST-GRADUATE HOSTEL:
CLINICAL REMINISCENCES.

ON Nov. 1st Sir JAMES DUNDAS-GRANT gave, at the Post-Graduate Hostel, Imperial Hotel, Russell-square, an address entitled Clinical Reminiscences.

Like a certain set of comedies, he said, clinical reminiscences might be classified as pleasant and unpleasant, whilst a further group might be added under the heading of "peculiar." Among pleasant reminiscences he could recall many cases of vertigo of the Ménière type relieved by ossiculectomy or by small doses of quinine. In some of them the patients had had fulminating epileptiform attacks and cholesteatomatous changes in the middle ear, particularly in the attic where the desquamative products were shut in by the ossicles. In these cases removal of the ossicles had permitted free escape of the accumulations and complete relief from the attacks. It was sometimes asked whether hearing was destroyed by the removal of the ossicles. Sir James Dundas-Grant answered this question by showing a case in which the ossicles had been removed because of persistent attic suppuration. Before operation the deafness was very considerable but now the patient could hear a soft whisper at the distance of 18 feet.

The value of small doses of quinine, continued Sir James Dundas-Grant, had been shown in many cases referred to the ear department of the West End Hospital for Nervous Diseases. In a large proportion relief had followed the administration of doses as small as one-half or even a quarter of a grain thrice daily, the vertigo returning when the quinine was omitted and disappearing again on its resumption. By Bárány's caloric test it had been found that the quinine acted as a sedative to the labyrinth of the healthy side.

The lecturer then demonstrated the method of testing the activity of the labyrinth by means of cold air. He regarded it as very effective and devoid of the discomfort and danger attending the use of cold water for the purpose. Nystagmus to the opposite side, with vertigo, postural deviation, and past-pointing to the same side was induced in normal persons in 29 or 30 seconds; but in a patient with nerve-deafness, who was shown, no reaction could be produced in over a minute and a half. To test the state of the nerve trunk galvanism was useful; one electrode was placed on the ear to be tested, the other on an indifferent part of the body, such as the back of the neck. If the cathode was applied and the current increased to 10–14 milliampères a definite nystagmus usually developed to the same side ("comes to the cathode"). The process, however, was very unpleasant and with a few milliampères a swaying of the body to the opposite side could be induced, showing the functional activity of the nerve.

Among less pleasant reminiscences, continued Sir James Dundas-Grant, were those of obstinate tinnitus aurium in which no gross aural cause could be detected. In some of these the application of the anodal galvanic pole—about 5 milliampères for five or ten minutes—afforded relief. The cathode could be placed on the hand and a binaural rheophore might be used for conveying the anodal current to both ears simultaneously. Care had to be taken to avoid an anodal opening shock. A special type of complaint was pulsating tinnitus synchronous with the pulse. When this tinnitus could be checked or diminished by pressure on the vertebral arteries in the suboccipital triangles it was often due to vasomotor disturbance and responded to bromides. He demonstrated the method of exercising compression on the arteries with the thumb and middle finger of one hand, whilst making counter pressure on the forehead with the other hand.

He had pleasant reminiscences, he said, of cases of obstinate deafness due to extreme catarrhal narrowing of the Eustachian tubes, in which unexpected improvement had followed the use of Weber-Liel's fine intratympanic tube passed through the Eustachian catheter when simple catheterisation had been quite ineffective in his hands and those of others.

For prophylaxis against tonsillitis Sir James Dundas-Grant advocated the use of thymol water as a gargle, and in reply to a suggestion that fluids used as gargles did not reach the tonsils, he demonstrated von Troeltsch's method of gargling, in which, with the head thrown back and the mouth kept open, the fluid was submitted to the movement of swallowing without, if possible, any being allowed to go down the throat. He had tested this method by having a culture taken from his own tonsils before and after gargling with thymol water; the colonies were extremely numerous before and almost absent afterwards.

Among peculiar reminiscences, he recalled a case of cough attributed to tuberculosis of the larynx, in which no laryngeal disease had been found but only symptoms of abscess of the liver, and a case in which suffocative attacks in a male infant were not due to presumed laryngeal obstruction but to spasm of the glottis associated with priapic manifestations afterwards cured by circumcision.

PASSPORTS FOR THE ITALIAN RIVIERA.

THE recent provision of the Italian Government with reference to passport regulations does not affect intending British visitors to the Italian Riviera. Dr. H. J. Spon writes from Ospedaletti to say that they are now, as always, heartily welcomed throughout Italy.

The Government luxury tax on hotel bills has been abolished, while the Communal Taxe de Séjour remains in force, and, in Ospedaletti, for example, has been fixed at rates varying from 50 centesimi to 2 lire per day per person, according to the class of hotel. This tax must be paid for any period up to 50 days, after which time no further payment is necessary throughout the season. In Ospedaletti pension terms are the rule; in the smaller hotels, 35/40 lire per day per person; in the more pretentious, 50/70 lire, while two single rooms, or a double-bedded room, with bathroom, can be secured on terms ranging from 110/150 lire per day. Arrangements can be made also to include the small additional charge for central heating and the 10 per cent. service tax.

ACCIDENTS WITH ELECTRICITY.

So few accidents are reported from the use of electric light and heat that most people have forgotten that a current of 100–250 volts laid on for domestic purposes may prove as dangerous as the high-tension supply which inspires respect in everyone. Dr. A. Zimmern has contributed to a recent issue of the *Bruxelles Médical* a long article on the way in which domestic accidents may be caused and prevented. Most mishaps, he says, come about through the tendency of all currents to go to earth. If the insulation of a switch or lamp is broken down and the metallic part is in contact with the supply of electricity, anyone touching it may act as a bridge through which a large proportion of the current returns to earth. Linoleum or carpet may block the path of the current, but a person standing on a floor of damp concrete or wet earth will certainly get a severe shock. Hand-lamps with a flexible lead are thus responsible, says Dr. Zimmern, for a good many deaths, and it is especially risky to hold a lamp in one hand and turn on a water-tap with the other. It is even more dangerous for anyone in a bath to handle electric apparatus, whether alight or not, for the bath is a perfect earth and the soaked skin so excellent a conducter that quite an insignificant current is enough to cause death.

It seems that a subject whose attention is concentrated suffers less from a shock than one who is relaxed, but, curiously enough, this rule does not apply to the relaxation of sleep. An anæsthetised rabbit remains unharmed by a current that would kill a conscious rabbit, and men who have been struck, whilst asleep, by fabulously high voltages have awakened slightly stunned, but unhurt. Cardiac debility, says Dr. Zimmern, does not add to the danger of a shock, and it is not clear why some people are not more susceptible than others. According to most authorities the immediate effect of a shock is to inhibit respiration by its action on the medulla, and the first-aid treatment is, therefore, artificial respiration. Jellineck states that hardly anyone is killed outright by electric shock, and that there would be few deaths if prompt and adequate treatment were applied. The asphyxiation, especially in shocks from low voltages, can also be due to tetanisation of the respiratory muscles. Oliver and Bolam, however, found in 1898 that when an animal was subjected to an electric shock the first effect was a stoppage of the heart and a tremor of the fibrils of the ventricle, with secondary asphyxia. This fibrillary tremor is not necessarily fatal to animals; how it concerns man is still a matter of theory.

The first act of the rescuer must be to cut off the supply. Sometimes a man surprised when working on high cables hangs by his hands in a state of spasm, and the circuit should not be broken until his descent has been provided for. It is disastrous to handle a person who is still in contact, as he is for the time being a live wire himself. If the current cannot be cut off, rescue may be tried by means of a piece of wood or a rope, but they must be dry. An electrocuted patient is to be treated as if drowned. Animals have been revived by heart massage and intracardiac injections of camphor, but the result of this treatment in man remains to be reported. The Schäfer method of resuscitation is still the best, and should be started at once. It has the advantage over Sylvester's method that it is less exacting to the operator and does not require extension of the tongue. The Panis artificial respiratory apparatus, which is worked by a lever and can be used for hours on end with little fatigue, is invaluable for these cases. The movements should be continued as long as there is no positive evidence of death. Dr. Zimmern recalls how an electrician once described to

him his anguish when, on the verge of recovering consciousness after a severe shock, he heard, as from afar off, one of his rescuers remark, "Better give up. He'll never come back."

CONTRACEPTION TEACHING AT WELFARE CENTRES.

THE following letter has been addressed to the hon. secretary of the League of National Life :—

Ministry of Health,
Whitehall, S.W. 1.
18th November, 1926.

SIR,—I am directed by the Minister of Health to refer to your letter of the 16th instant in regard to the policy of the Ministry of Health in relation to the giving of information in reference to methods of contraception at maternity and child welfare centres, and to state that the Minister has, in agreement with his predecessors, adopted the policy with regard to this matter which is set out in the following paragraphs :—

(1) That the maternity and child welfare centre should deal only with the expectant and nursing mother (and infant) and not with the married or unmarried woman contemplating the application of contraceptive methods.

(2) That it is not the function of an antenatal centre or a maternity and child welfare centre to give advice in regard to birth control, and that exceptional cases in which the avoidance of pregnancy seems desirable on medical grounds should be referred by the medical officer of the centre for particular advice to a private practitioner or hospital.

I am to explain that this reference of exceptional cases by the medical officer of a centre is a wholly different matter from the giving of contraceptive advice and instruction at the centre itself, and that such reference should be made only on medical grounds by the medical officer of the centre and not by voluntary helpers or nurses on general social grounds.

I am, Sir, your obedient Servant,
(Signed) E. L. PUXLEY.

THE "S.O.S." SUGAR BASIN.

WE have received from Messrs. Joseph Gilbert and Sons, Sun Works, Bissell-street, Birmingham, a sugar-basin which has been designed to keep the contents free from dust and from contamination by flies by providing an ingenious close-fitting lid. Attached to the inside of the lid is the sugar-tongs, constructed on the principle of lazy tongs, while the handle for working this part of the apparatus, placed outside the lid, forms also the handle for lifting the lid from the container. The invention, which is made in silver or other kinds of plate, should find a place among hygienic contrivances in the home and certainly in hotels and restaurants.

INDUSTRIAL ILLUMINATION.

WE have received from the Department of Scientific and Industrial Research three technical papers on Illumination Research. The object of the first, entitled "The Terminology of Illumination and Vision" (H.M. Stationery Office, 1926, pp. 21, 9*d*.), is to acquaint readers of the reports published by the Illumination Research Committee with the exact definition of the technical terms used both by the physicists and the physiologists engaged in the various researches. For the former, Mr. J. W. T. Walsh, of the National Physical Laboratory, has made himself responsible, the physical terms needing definition including such expressions as "luminous flux," "brightness," and "international candle." On the physiological side Dr. W. S. Duke-Elder explains the chief technical terms employed in physiological optics, including such matters as the light, form, and colour senses and retinal adaptation. The other papers deal with the Transmission Factor of Commercial Window Glasses, by A. K. Taylor, A.G.G.I., and C. J. W. Grieveson, M.A., B.Sc., of the National Physical Laboratory (pp. 10, 6*d*.), and Light Distribution from Industrial Reflector Fitting No. 1, by H. Buckley, B.Sc., and C. J. W. Grieveson (pp. 26, 1*s*.).

THE CORKSCREW.[1]

A BETTER knowledge of the history of wine would assist in the public appreciation of the teetotal question, though many economic problems have to be solved before light wines can be drunk in this country in the manner that they were before the corkscrew was invented, and when rich and poor alike could sing metrical toasts while consuming claret out of elegant glasses. The bottlescrew was the original name of the corkscrew, and the significance of its appearance early in the eighteenth century is that previous to that date wine was a draught beverage, and was consumed from the cask. On the introduction of bottling with cork stoppers, the corks were made conical, and more than half of their substance was left above the neck of the bottle, so that the plug could be extracted by the fingers. Bottles could not be laid on their side, nor the process of maturing as we now understand it carried out. When corks were driven home flush with the necks of cylindrical bottles fit for storing in bins, the corkscrew arrived. As a whole-hearted advocate of wine-drinking, Mr. Simon naturally points to the political schemes for crippling the trade of France as the cause for the bestial drunkenness which afflicted society when Hogarth's relentless pencil drew the degradation of our gin-sodden populations. Home-brewed ale and imported clarets were then replaced by ardent spirits, and fortified port became the beverage of the rich. Gin, British brandy, and home-made cordials, Hollands from the Low Countries, and arrack from the colonies, were freely imbibed by all classes, while a highly-organised trade in smuggling procured French brandy duty free. How important a part smuggling played in the history of England during the eighteenth century can be gathered from the portentous figures which Mr. Simon gives in illustration of successful defiance of the law. A curious side-light is thrown on drinking habits among persons in the highest political positions when we learn of a practice, which lasted to the end of the eighteenth century, in spite of the protests of the Board of Customs, under which all duties on wine imported by British diplomats and political men when returning home from an embassy or from a mission abroad were remitted.

This book is full of accurate and curious information on wine-drinking in England during the eighteenth century, and the written story of social life during the period is embellished with some well-chosen and amusing pictures.

[1] Bottlescrew Days: Wine-drinking in England during the Eighteenth Century. By André L. Simon, F.R. Hist.S. London: Duckworth and Co, 1926. Pp. 273. 21*s*.

BATS, BUGS, AND PRUSSIC ACID.

BATS were becoming a nuisance in an unfinished attic of a house in the Edgewood Arsenal, the bats were infested with bed-bugs and lice, and the successful attempt to get rid of them all is narrated in the *Military Surgeon* for October by First-Lieut. H. A. Kuhn, of the Chemical Warfare Service. As bats have a certain economic value, being insectivorous, it was first sought to clear them out by laying chloride of lime about, and when that failed, by tear gas. These measures proving unsuccessful, it was decided to use hydrocyanic acid and cyanogen to kill both the bats and their parasites. As the roof of the attic was unfinished it seemed necessary to use these gases in three times the ordinary strength to ensure killing the bats and their parasites quickly. The attic contained 4000 cubic feet, so six three-gallon crocks were placed round the floor, and in each 1500 c.cm. of commercial hydrochloric acid, diluted with an equal quantity of water. Into each of these, at 1.40 P.M., a man, protected by a suitable gas-mask, dropped two packets, each of 6 oz. sodium cyanide, with 3 oz. sodium chlorate, coarsely ground and done up in cheese cloth, and then left the attic, sealing the door, which was not opened till 18½ hours later,—at 8.10 next morning. Two bats flew out at once, and four others a few minutes later, but these latter dropped, dead, on the ground. Temperature was about 80 deg., and there was a slight drizzle, but no wind. A little lacrymation was noted among people close outside. When the attic was opened there was but a slight odour of gas. No bats survived; 260 dead bats were counted; their parasites were all killed. The possible danger to human life being so great, preventive measures should always be in readiness. In addition to fresh air, intravenous injection of sodium, thiosulphate ("hypo") is recommended as the best antidote, in 25 per cent. solution, to be kept ready in a 5 c.cm. syringe. No one unprotected by a suitable mask should be in the neighbourhood.

LACRYMAL SECRETION AS A BACTERICIDE.

Dr. Michael Grabham, of Madeira, has addressed a brief statement to the Medical Research Council and the British Empire Cancer Campaign detailing the apparently good results which have been obtained by Dr. F. Pitta, of Funchal, in the treatment of 17 cases of malignant disease with trachoma exudate. The lacrymal secretion has been shown by Dr. A. Fleming to possess certain bactericidal powers and Dr. Grabham attributes Dr. Pitta's happy clinical results to the influence, mainly, of the diplococcus ascertained by Dr. Fleming to be present in lacrymal secretion and named by him *Micrococcus lysodeikticus*. Of the 17 cases treated by Dr. Pitta only two are mentioned in Dr. Grabham's communication with any detail, but one of these, a case of inoperable cancer of the cervix uteri, forms a striking story. Dr. Grabham's pamphlet is in substance a plea for further research directed to verify the imputed inhibitory energy of the natural lacrymal outflow.

Dr. Crookshank writes to say that the quotation from the Latin version of Galen (18–2–24) that prefaced his Bradshaw lecture (reported in THE LANCET for Nov. 6th, p. 939) should run as follows: "Verumtamen praesentium rerum cognitionem proprio nomine *diagnosin*, hoc est dignotionem, appellare consuevimus."

Messrs. Watson and Sons (Electro-Medical), Ltd., of London, have reprinted an article from the *Electrical Review* describing the equipment furnished by them to the new radiological department of the Edinburgh Royal Infirmary.

A Lecture
ON
HIGH BLOOD PRESSURE
FROM THE CLINICAL ASPECT.

Given at St. Andrews (James Mackenzie) Institute for Clinical Research on Oct. 19th, 1926,

BY SIR HUMPHRY ROLLESTON, BART., K.C.B., M.D. CAMB., F.R.C.P. LOND.,
REGIUS PROFESSOR OF PHYSIC IN THE UNIVERSITY OF CAMBRIDGE.

HIGH blood pressure is a sign not a disease, and may, of course, appear temporarily as the result of transient mental emotion or toxæmia. But the form of high blood pressure that will be conveniently considered in connexion with the title "High Blood Pressure from the Clinical Aspect" is fairly constant, and corresponds to the condition called hyperpiesia by the late Sir Clifford Allbutt; this is the essential or idiopathic hypertension of American medicine. The word hyperpiesis was confined by Allbutt to the rise of blood pressure.

CLINICAL MANIFESTATIONS ASSOCIATED WITH HIGH BLOOD PRESSURE.

In the first place it will be advisable to consider the clinical manifestations that may be associated with high blood pressure alone, not "the symptoms of high blood pressure" (for, strictly speaking, the phrase clinical manifestations of a symptom is meaningless)—namely, in a person without any cardiorenal complications or arterio-sclerosis. What symptoms can be rightly associated with an abnormally high blood pressure? Are they directly due to it? Or are they concomitant results of the factor responsible for the high blood pressure? Because if the symptoms found in patients with a high blood pressure are due to a uræmic toxæmia or to a resulting or complicating arterio-sclerosis, a lecture on the clinical symptoms solely due to high blood pressure might appear to be like that of the famous chapter in Horrebow's "Natural History of Iceland," "There are no snakes to be met with throughout the whole island."

The physiological high blood pressure accompanying active physical exercise, the frequent freedom from symptoms in persons found to have high blood pressures in routine examinations, as for life assurance, and the malaise that may follow its too energetic reduction, are arguments in favour of the view that high blood pressure is a compensatory mechanism (Osler), for example, to prevent anæmia of the brain and medulla; and that some underlying disorder, metabolic, infective, or even of structural origin, makes it necessary that the individual's blood pressure should be set higher than that of the ordinary healthy person. This attractive explanation is hard to disprove.

The question whether or not the symptoms ascribed to high blood pressure are toxæmic and due to a concomitant or the same factor as the high blood pressure is difficult, but some light may be thrown on it by the following considerations. One conceivable method of arriving at an a priori notion of what symptoms might be anticipated solely from an unduly elevated blood pressure is to take the clinical manifestations associated with unduly low blood pressure (below 100 mm. Hg) in persons without obvious reasons for it, such as Addison's disease, cachexia, and malignant disease, and then to call to mind the exactly opposite manifestations. The symptoms associated with essential hypotension are somewhat vague, but are mainly loss of vigour—mental and bodily—easily produced fatigue, nervous instability, dizziness and giddiness, liability to faintness, insomnia, vasomotor instability, and sensitiveness to cold. In latent high blood pressure—namely, without any subjective discomfort—there is often, if not usually, a sense of well-being and energy. On the other hand, Sir Clifford Allbutt mentioned as symptoms of hyperpiesia, whether renal or non-renal, matutinal depression, languor, apathy even to torpor, fatigue, vertical headache or fullness or weight on the head, insomnia, beating of the heart, especially felt at night on the pillow, and added that in the hyperpietic patient these discomforts may be relieved by a blue pill, but not in the victim of renal disease in whom they are uræmic. Some symptoms, for example, tired feelings, headache, and giddiness, are common to subnormal and supernormal blood pressure, and it would seem reasonable to suggest that in both conditions they are due not so much to the abnormal blood pressure as to their causal toxins, pressor or depressor. This is supported by the late R. W. Michell's observations on the average low blood pressure, often nearly 110 mm. systolic (which some authorities (Fossier) regard as hypotension) of athletic undergraduates at Cambridge, who certainly do not suffer easily from muscular fatigue

As a high blood pressure is often found in the routine examination, as for life assurance, of persons who feel perfectly well, this might be held to justify the generalisation that a high blood pressure without any other factor, whether chemical, such as toxæmia, or structural, such as arterio sclerosis, does not cause symptoms. Before arriving at such a final conclusion it is worth consideration how far the varying sensitiveness of individuals may determine whether or not they react to stimuli or remain unconscious of them. About the existence of such variation in the response to stimuli there, of course, cannot be any doubt. Libman has described a simple physical test by which individuals can be divided into the hyposensitive, the normally sensitive, and the hypersensitive, according to their sensations when pressure is exerted by the thumb on the styloid process of the temporal bone (and the great auricular nerve). Some persons do not experience any pain (hyposensitives) and others a great deal (hypersensitives). He explains the syndrome of angina sine dolore by the hyposensitive character of the patient. If by analogy this is applied to high blood pressure it would appear that in the earlier stages of the condition a large number of persons are hyposensitive and that in the later stages they become hypersensitive. Though at first sight this may seem an unwarrantable assumption, it is not inconceivable, that if, as is probable, high blood pressure is often due to toxins derived from protein splitting, their continued action on the nervous system might lead to a condition of hypersensitiveness.

Although persistent high blood pressure may for a long time be unaccompanied by any symptoms, the question arises as to the existence, though it cannot be detected by physical examination, or even by renal efficiency tests, of early structural changes in the kidneys or blood-vessels, especially of the medulla oblongata. F. M. Allen states dogmatically that high blood pressure never exists with normal kidneys, but qualifies this by admitting that even in rather severe and long-standing hypertension the renal lesions may be limited to such slight changes in the small arteries that only close study reveals them. O'Hare and Walker compared 50 cases of arterio-sclerosis in which the renal arteries were affected and there was a raised blood pressure, with 50 cases of general arterio-sclerosis without either disease of the renal arteries or high blood pressure. Other evidence does not tend to support the exclusively renal origin of high blood pressure; in 72 cases Fishberg found the renal arteries affected in 65 per cent., and these were obviously cases in a late stage.

As has been shown by Starling and Anrep, impairment of the blood-supply to the vasomotor centre in the medulla at once calls forth a compensating rise in blood pressure. A definite association of arterio-sclerotic changes in the medulla with high blood pressure appears to be shown by Bordley and Baker's examination of 24 cases of generalised

arterio-sclerosis; 14 of these with high blood pressure during life constantly showed arteriolar sclerosis in the medulla oblongata and in the kidneys; in the remaining 10, with a normal blood pressure in life, the arterioles in the medulla were healthy at the necropsy. As cerebral arterio-sclerosis may exist without peripheral arterio-sclerosis, it is possible that some cases of high blood pressure are due to sclerotic changes limited to the basilar artery and its branches; but it is unlikely that such arteriolar lesions in the medulla would precede and last so long, as they would have to do in many cases, before producing other nervous symptoms. On the other hand, it is conceivable that some poison to which the vessels of the medulla are susceptible, in a way analogous to imperfectly oxygenated blood, may lead to their vaso-constriction, and so induce a general rise of blood pressure.

It may be noted that, although evidence of retinal arterio-sclerosis is a good guide to the presence of the same change in the brain (Foster Moore, 1916), retinal arterio-sclerosis has been described microscopically when not previously detected ophthalmoscopically (Cohen).

CLINICAL PICTURE.

It is not proposed to consider the much-discussed ætiology of high blood pressure, but there is a subject midway between ætiology and the clinical picture—namely, the anthropometric characters of persons affected with this condition. The hereditary tendency to high blood pressure is well established, and, according to Alvarez, it is a bodily peculiarity inherited equally by boys and girls, but with its manifestations in the female sex delayed until the menopause. Structure and function are so closely inter-related that the "constitution" of a hyperpietic may well show physiological variations from the normal in the direction of exaggerated vasomotor response (Dawson) as well as physical characteristics. Although the make-up or constitution of the body only favours the incidence, and does not indicate the existence, of high blood pressure, the presence of these characteristics enters into the clinical picture of the disorder, and enters into the composite picture which is so quickly recognised in the process of making a facial diagnosis. George Draper has applied the most accurate anthropological methods to the problems of disease, and investigated the physical characters of a number of diseases, one of which is the group of nephritic and high blood pressure patients, based on complete examination of 19 males and 20 females, and it is noteworthy that the characters often differ in the sexes. The time is hardly ripe for a final characteristic picture of the subjects of supernormal tension, but a few of Draper's conclusions may be quoted. The males are small and have the shortest heads, whereas the females are very large, have protruding upper teeth, are heavy faced, more masculine, have longer heads as compared with other disease groups, and, showing physical signs on the lines of acromegaly and previous pituitary activity, are more prone under the specific stimulus of pregnancy to develop high blood pressure or nephritis. Both sexes have the short necks popularly associated with apoplexy. The statistics of the Life Extension Institute of New York show that overweight is more often than a normal weight associated with high blood pressure, but that the incidence of arterial sclerosis in the adipose hypertensives is lower than in normal persons. Possibly this rather unexpected result may be due to difficulty in palpating the radial artery in stout people (Dublin, Fisk, and Kopf). In women about the menopause obesity and high blood pressure often go together, and according to Garvin these two conditions are probably associated results of some underlying factor; he found high blood pressure in 33 per cent. of 200 obese persons, two-thirds of them being women, as compared with 12 per cent. among non-obese controls.

Slightly modifying Lewellys Barker's paradigm of high blood pressure in four groups corresponding to four successive periods common to all the cases, the following stages may be suggested:—

1. Early high blood pressure without any cardiac, arterial, or renal changes as far as can be determined.
2. In which hypertrophy of the left ventricle, but no discoverable arterio-sclerosis, has resulted.
3. In which arterio-sclerosis and renal fibrosis have followed continued high blood pressure, and give rise to the complications in
4. The brain, arterio-sclerotic changes, cerebral hæmorrhage; kidney, chronic interstitial nephritis, uræmia; heart, myocardial failure.

Such a division into stages has the advantage of distinguishing between high blood pressure alone on the one hand and its results and complications on the other. In attempting to estimate the symptoms solely due to high blood pressure, those in the last two groups—namely associated with resulting arterio-sclerosis—must, of course, be excluded. Leslie T. Thorne has also classified cases into four groups, according as the high blood pressure is or is not associated with arterial change, and according as the heart is or is not dilated as a result of the unusual strain.

It will be advisable to discuss separately the physical signs and the symptoms that have been ascribed to high blood pressure with the object of determining how far they can be regarded as solely due to it.

Physical Signs.

The diagnosis, of course, depends on one physical sign—the raised blood pressure taken with precautions to avoid the high blood pressure due to excitement. Very considerable variations in blood pressure may occur from time to time, and this instability is a feature of supernormal pressure. Accentuation of the aortic second sound, on which considerable reliance was placed in the days before the vogue of the sphygmomanometer, is not such an absolutely accurate sign of increased blood pressure, as it occurs as the result of atheromatous dilatation of the first part of the aorta.

Hæmorrhages in various positions are occasionally seen in persons with high blood pressure; but that they are due solely to it and independently of gross vascular lesions, such as arterio-sclerosis and of toxæmia, appears improbable from their infrequency in uncomplicated cases. A sign of importance, though often depending on some local conditions, such as ulcer, angiomatous or other change in the vessels, is a sudden hæmorrhage from a mucous surface (epistaxis is the commonest), and may come as a very unpleasant and ominous surprise to a man who believed himself to be in perfect health. Epistaxis may, it is said, occur in high blood pressure without any evidence of a local cause, such as n ulcer. Profuse gastro-intestinal hæmorrhage is much rarer, and naturally suggests a peptic or other ulcer, but this does not appear to explain all the cases. Rudolf records the case of a man without evidence of renal disease or arterio-sclerosis who with a blood pressure of 180/110 had severe hæmatemesis on three occasions; after the first his abdomen was opened, but no cause was found; after the other attacks he felt better and his pressure was 150/100. Non-tuberculous hæmoptysis has been described in supernormal blood pressure (Allbutt; F. de H. Hall; Rossi); it is analogous to epistaxis, and recalls Andrew Clark's "non-tuberculous and non-cardiac hæmoptysis of elderly persons." It would be natural to ascribe these to some structural change, such as emphysema or arterio-sclerosis, especially in elderly persons, but Allbutt considered that they might occur independently of any local vascular disease.

Retinal hæmorrhages are common in persons with high blood pressure and arterio-sclerosis, but the question arises whether or not they ever occur in high blood pressure without any vascular change. As the condition of the arteries of the retina have been more carefully and frequently examined than those of the nasal and gastro-intestinal mucous membranes, a decision on the question whether or not local vascular

disease is responsible for hæmorrhages in high blood pressure can, perhaps, be obtained with the assistance of ophthalmologists. It appears probable that high blood pressure alone is not sufficient to cause hæmorrhages from healthy vessels, but that given vascular disease, whether arterio-sclerotic or acutely toxic, hæmorrhages are more likely to occur with a high blood pressure.

Mr. Foster Moore argues that they are due to disease of the vessel wall and not to high blood pressure alone; his reasons for this are that they are very common in arteriosclerosis and after retinal thrombosis, which is usually the result of local vascular disease (1924), and in leukæmia, pernicious anæmia, and rapidly produced secondary anæmia in which there is not any rise of blood pressure; that they may rapidly increase towards the end of life without any corresponding rise of blood pressure (1917); and that in arterio-sclerosis the blood pressure is not raised in the retinal arteries (1916). He also finds that the women among his cases were more tolerant of high blood pressure, as judged by survival, than men. Dr. Anthony Feiling has reported 100 cases of hyperpiesia, arterio-sclerosis, and chronic renal disease with retinal changes or vitreous hæmorrhages, in which the visual defect was the chief and generally the only symptom; he has kindly informed me that, while it is very difficult to exclude vascular change, high blood pressure, though an important auxiliary factor, is not likely to be the sole cause of retinal changes; but he considers that retinal hæmorrhages are very uncommon, even in well-marked general arterio-sclerosis, in the absence of high blood pressure. Dr. Maitland Ramsay writes that with healthy retinal vessels there is not much risk of intraocular hæmorrhage.

This question of hæmorrhage in high blood pressure is obviously important in connexion with cerebral hæmorrhage; the conclusion that hæmorrhage does not occur except when the vessels are damaged appears to hold good also with regard to intracranial hæmorrhage.

The Rumpel-Leede phenomenon—namely, the appearance of minute petechial hæmorrhages in the skin distal to the area of pressure after the estimation of blood pressure—is rare in my experience; as it is said to occur also in menstruating women, scarlet fever, and chronic infective endocarditis (Weissmann) it cannot be regarded as pathognomonic of high blood pressure, and is very probably due to endothelial degeneration.

Blood.

It is not uncommon, in spite of the frequency of pallor in persons with supernormal blood pressure, to find some degree of polycythæmia; Lenaz found that the red count varies with the systolic pressure in a constant manner, there being a quotient of 25 between the systolic pressure expressed in millimetres of mercury and the number of millions of the red cells; thus blood pressures of 125, 150, and 170 are associated with red counts of 5, 6, and 6·8 millions. But this hardly holds good. In the cases described as polycythæmia hypertonica (Geisböck), of which Parkes Weber has collected eight with blood counts and blood pressures, there is certainly a general but not absolute agreement with this rule, but by definition there must be both polycythæmia and high blood pressure. It appears that these cases are usually complicated by chronic interstitial nephritis. Differences in the association of high blood pressure and increase in the number of red cells may be explained on the grounds (1) that increased viscosity of the blood in erythræmia may raise the blood pressure, and (2) that increased arterial blood pressure does not alone raise the red count, but only when associated with a rise in the capillary pressure which then leads to concentration of the blood and a fall in its water content (Lomaz). In pure hyperpiesia (without any renal disease) Boas and Frant state that the capillary pressure was not raised; Kylin found the capillary pressure high in glomerular nephritis but not raised in granular kidney. From these observations it might appear that the red count depends on a factor additional to high arterial blood pressure—namely, one, such as glomerular nephritis, which raises the capillary pressure.

Increased excretion of urine and nocturnal micturition are direct and physiological results of raised blood pressure, but the specific gravity of the urine is not necessarily lowered.

The metabolic rate in high blood pressure would, from the observations of Aub and Dubois and of Shapiro, appear not to be raised unless dyspnœa is present.

The Relation between High Blood Pressure and Hyperglycæmia.—In 1910 Neubauer found hyperglycæmia in a large proportion of the cases of very high blood pressure, and ascribed this to excessive adrenal activity. Von Noorden accepted this, but subsequent observers rejected it, finding that very high pressure may exist without hyperglycæmia. But hyperglycæmia without hypertension is infrequent. G. C. Linder, A. Hiller, and D. D. van Slyke conclude that there is not any constant relation between high blood pressure and hyperglycæmia, and Herrick isolates a group of cases with high blood pressure, hyperglycæmia, obesity, and arterio-sclerosis, thus suggesting rather widespread metabolic disorder; Westphal found the cholesterol-content of the blood raised in 71 per cent. of persons with a high blood pressure, and believed that the cholesterol excess caused the raised blood pressure, but it might be regarded as the result of accompanying arterio-sclerosis.

A Beating Leg.—According to Molle, oscillation of the leg when crossed over the other knee, as in testing the knee-jerks, shows that the blood pressure is over 160 mm. Hg. But this phenomenon, so familiar in aortic incompetence, would appear to depend on a large pulse pressure. The late Sir Clifford Allbutt told me that he had had it all his (noticing) life, and that he had a slow pulse (48-52) and a large pulse pressure, or, as he preferred to call it, differential pressure.

A new physical sign of high blood pressure has been described by Brown and Rowntree, of the Mayo Clinic; it is said to occur only in women, and not to occur in arterio-sclerosis. It consists in pulsation in the lower part of the neck on the right side, and may imitate aneurysm. It depends on elevation of the aortic arch, which, therefore, lifts up the right subclavian artery and kinks or buckles the right common carotid artery.

Transient arterial spasm, comparable with that in Raynaud's disease and migraine, has been thought to explain, by the resulting anæmia of cortical areas, temporary aphasia, amblyopia, hemiplegia, mental confusion, and loss of memory (Pal; W. Russell; Williamson); nitrite of amyl and vasodilators have therefore, been recommended for these slight strokes, cerebral crises, or cerebral eclipses as they have been graphically called. On the analogy of Raynaud's disease and migraine, which may show visible spasmodic contraction of the arteries of the retina, which is a prolongation of the brain, this comforting explanation of simple spasm seems to be quite reasonable, but it is probable that there is often more behind—namely, arterio-sclerosis of the cerebral vessels. Osler bracketted high blood pressure with arterio-sclerosis as the cause of these transient cerebral seizures in a paper recording their duration for five years in a medical friend with "arteries like whip-cord," and mentioning that he had seen a score or more cases, in three of which there was no palpable arterio-sclerosis. In the intervals between the attacks the general health may be perfectly good, and possibly there are several causes for these seizures—viz., simple migrainoid spasm in some, probably few, cases; in some "uræmic" or toxæmic spasm; more often cerebral arterio-sclerosis, or even minute areas of softening or of hæmorrhage. Some authorities (Peabody) believe that arterio-sclerotic vessels are more prone than healthy ones to undergo spasmodic contraction and that anginoid pain may be due to spasm, set up by tobacco or other stimuli, of the sclerosed coronary arteries, or that colic, or angina abdominis, may be due to a similar process in the mesenteric arteries.

The late Sir Clifford Allbutt discussed these transient strokes on two occasions at some length, and ascribed them to tiny hæmorrhages, giving examples of such lesions found after death, and pointing out that they may be recognisable only on microscopical examination; he was vigorously opposed to the responsibility of arterial spasm and local œdema, and the view that a terio-sclerotic vessels are more prone than healthy ones to spasm. A clinical justification for the view that these slight strokes are due to minute hæmorrhages is the frequency with which these slight strokes are followed by undoubted cerebral hæmorrhages.

Hypertrophy of the left ventricle, which is a compensatory effect of continued high arterial blood pressure, may be followed by cardiac dilatation and insufficiency. Arterio-sclerosis is another effect of high blood pressure; it and cardiac failure produce their own series of symptoms, which, being indirectly derived from high blood pressure, do not come within the scope of the present, perhaps artificially, restricted discussion—namely, the symptoms of raised blood pressure alone.

Shortness of breath on exertion, often stated to be an early symptom of high blood pressure, was very definitely regarded by Sir Clifford Allbutt as evidence that the patient has entered upon the last stage of his malady and of myocardial strain. My own impression is that this dyspnœa is a phenomenon of the stage when well-marked arterio-sclerosis has supervened; but this may not be invariably true. The diaphragm is usually high in fat people, and Leonard Williams explains the dyspnœa of obese hyperpietics as due to interference with the descent of the diaphragm by the omental accumulation of fat, and refers to the "basitis," described by Heckel, or localised œdema at the base of one or other lung caused by abdominal lipomatosis. It is obviously necessary to bear in mind other causes of dyspnœa, such as emphysema.

SYMPTOMS.

Numerous subjective symptoms have been ascribed to high blood pressure, but very often the distinction between pure supernormal pressure and what has been called organic hyperpiesia—namely, complicated by arterio-sclerosis—has not been borne in mind. This applies, perhaps, particularly to some of the nervous symptoms, as has been seen in regard to transient paralyses.

Headache due to high blood pressure is often mentioned, but is there any evidence that it is solely due to this cause and not to the toxæmia connected with the supernormal pressure? In favour of the direct causal relation of high blood pressure is the relief obtained by some patients from amyl nitrite and vasodilators. The late Sir Lauder Brunton, from too frequent opportunities of studying it in his own person, explained the headache of migraine as due to proximal dilatation and peripheral contraction of the temporal artery. The cause of migraine is unsettled, but hypersensitiveness to some poison causing arterial spasm seems a reasonable hypothesis; the toxic nature of migraine, however, has not met with much support. Lumbar puncture relieves the headache of some persons with high blood pressure; if the increased amount of cerebro-spinal fluid was due to some interference with its removal, the resulting rise in the intracranial pressure would cause both the headache and, by rendering anæmic the vasomotor centre in the medulla, the rise of blood pressure. The familiar experience that some high blood pressure headaches are removed by calomel, salts, and the subsequent purgation, is in favour of a toxic origin. It is significant that headache is also found in people with a low blood pressure, thus suggesting that the headache both in the hypertensive and the hypotensive is toxic, and that any variations in the character of the respective headaches are due to the toxins being different—pressor and depressor.

Vertigo.—Spasm of the vestibular branch of the internal auditory artery, producing from anoxæmia hypersensitiveness of the vestibular receptors (Mills), or of other intracranial arteries, causing cortical anæmia, has been suggested as a cause of vertigo; but it is difficult, if not impossible, to exclude arterio-sclerosis of these vessels. Again, the direct action of toxins on the semicircular canals must be taken into consideration. Further, as vertigo is not a constant symptom of high blood pressure, and as it may be caused by toxæmia, it would appear to be more probably thus excited in hyperpiesia.

Sir Kenneth Goadby tells me that in a number of patients he has noticed vertigo to coincide with a difference in the systolic blood pressure in the two arms, the attacks of vertigo corresponding with this difference and disappearing when the blood pressures on the two sides become equal. This observation, the result of a systematic examination of the blood pressure in both arms and both legs, raises the questions of the causation of the difference in the blood pressure on the two sides and the mechanism of the production of vertigo; in Goadby's cases the intermittent character of the difference in the blood pressure on the two sides of the body suggests spasm or vaso-dilatation, and an analogy with migraine and the transient strokes. The significance of considerable variation of the systolic blood pressure on the two sides of the body varies, and when inconstant may perhaps have a bearing on Goadby's observations on vertigo, but in what way is very speculative.

Differences in the blood pressure on the two sides of the body may be due to anatomical abnormalities or arterio-sclerosis, and then is constant; it may also be found in hemiplegia, although usually slight in amount, and Dana associated this with thalamic lesions, there being a fall of blood pressure on the paralysed side due to vaso-dilatation. In pulmonary tuberculosis R. J. Cyriax found the systolic pressure unequal, usually lower on the affected or more diseased side; in unilateral trauma and in bilateral injuries of different degrees the systolic blood pressure varied on the two sides, but was not constantly higher on the same side (E. F. Cyriax).

Neurasthenic symptoms may be prominent with high blood pressure, but their frequent absence in high blood pressure makes it highly probable that they are due to an underlying toxæmia. Tingling in the hands and feet is toxic or uræmic in origin, and intermittent claudication or limp is fundamentally arterio-sclerotic, though no doubt superadded spasm may cause exacerbations of pain.

Cardiac pain of an anginoid character, on exertion, may occur in association with high blood pressure, and has been explained as the result of stretching of the first part of the aorta; but even so, it is difficult to exclude arterial changes in this part of the aorta and in the coronary arteries.

Abdominal Symptoms.—Some, such as flatulence, dyspepsia, "torpid liver," are rather doubtful, as they may be part of over-eating or gastro-intestinal toxæmia responsible for the high pressure and concomitant results. In rare cases periodic attacks of vomiting—migraine without the headache and ocular sensations—occur. Possibly some cases of abdominal pain, "angina abdominis," may be due to spasm of mesenteric arteries. "Angina abdominis," which was described in this country by Sir Lauder Brunton and by Parkes Weber, includes (1) angina pectoris with the pain referred to the abdomen, and (2) the analogue of intermittent claudication—namely, pain associated with arterio-sclerosis of the mesenteric arteries—but the important factor in intermittent claudication is the arterio-sclerosis, not the high blood pressure.

CONCLUSION.

On the whole it seems probable that high blood pressure alone is not a potent cause of symptoms, but that the association of symptoms, which is so widely recognised, is due either to the cause, such as toxæmia, of high blood pressure, to concomitant or resulting arterio-sclerosis, or to cardiac failure. But high blood pressure has important bearings on prognosis, as has been shown by the statistics of life assurance offices, and should always be the signal

for intensive investigation of an underlying cause—dietetic, psychological, environmental, toxi-infective, and renal. That it is a danger signal in puerperal toxæmia is well recognised.

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY.—The Carnegie Trust has made a grant of £500 towards the upkeep of this society, which was one of the oldest scientific institutions, founded in 1781 and is historically associated with the names and work of Dalton and Joule.

THE LATE DR. ALEXANDER LAWRENCE.—The death occurred on Nov. 23rd, at his residence at Hough Green, Chester, of Dr. Alexander Lawrence, at the age of 80. Dr. Lawrence was born at Cullen, Banffshire, educated at the University of Aberdeen, where he graduated M.A. in 1866, and M.D. in 1872. He was for a time house surgeon and superintendent at Chalmers' Hospital, Banff, and later a clinical clerk in the West Riding Asylum, Wakefield. In 1870, at the age of 25, he was appointed second assistant medical officer to the Chester Medical Hospital, where there were then about 500 patients. In 1895 he became superintendent of the hospital in succession to Dr. J. H. Davidson and during his period of service the number of patients increased to 1100. He retired on superannuation in 1910. Dr. Lawrence was a keen golfer and started the Bache Golf Club, of which he became the first president.

POST-SCARLATINAL MENINGITIS.*

BY J. GRAHAM FORBES, M.D. CAMB., F.R.C.P. LOND., D.P.H.,

DIVISIONAL MEDICAL OFFICER, PUBLIC HEALTH DEPARTMENT, LONDON COUNTY COUNCIL.†

IN view of the acknowledged rarity of meningitis as a complication or sequela of scarlet fever, the following case may be regarded as of sufficient interest to record, and so to rescue from oblivion:—

J. J. M., a girl, aged 6 years, was a patient at the South-Western Hospital from the middle of January, 1925, for close on two months. During this period she passed through an ordinary though sharp attack of scarlet fever, without other complication than adenitis in the third week, and evidence of ear trouble was conspicuously absent. She was discharged to her home on March 11th, and soon after complained of right earache. She remained otherwise apparently well for a period of three weeks, when she began to suffer from severe headache, which persisted, and was referred to the vertex. A week later pain and stiffness in the posterior cervical muscles developed, followed by profuse vomiting, and she became very drowsy.

On April 14th she was admitted to St. James's Hospital, Balham, in a semi-comatose state, with a temperature of 104·8° F. and typical signs of meningitis. She lay curled up in bed; there was marked cervical rigidity, conjugate deviation of the eyes to the right, and twitching of face and limb muscles. No ear discharge was noted. Kernig's sign was well marked, and the patellar reflexes were absent.

Lumbar puncture was performed on the 15th, and yielded a considerable quantity of cloudy fluid under great pressure. Death occurred on the following day, but consent to perform post-mortem examination was, unfortunately, refused.

Examination of the Cerebro-spinal Fluid.—Very turbid, faintly yellow fluid, yielding a fine viscid coagulum, and on centrifugation a heavy cell deposit. Albumin 0·1 per cent., globulin in excess, dextrose very faint trace. Stained film preparations from the clot and cell deposit showed abundant polymorphs, in marked excess of lymphocytes, and a few Gram-positive cocci in pairs and short chains. Cultivation of the fluid on agar yielded a scanty number of colonies of a long-chained streptococcus. Ample growth was, however, obtained in subculture on blood-agar of streptococcal colonies which were definitely hæmolytic. The blood-agar subculture was submitted to Dr. F. Griffith, bacteriologist to the Ministry of Health, who kindly undertook serological tests. He reported that the streptococcus was serologically identical with one of the strains isolated by Dochez in association with scarlet fever.[1] It was, moreover, the only homologue of the Dochez strain which had so far been found in this country, affording also the only instance apparently recorded in which *Streptococcus scarlatinæ* has been isolated and verified from the cerebro-spinal fluid.

Remarks.

The results of the serological tests would seem to demonstrate a clear link between the original attack of scarlet fever and the ultimate fatal meningitis. It is possible, if not probable, that post-mortem examination would have shown an intermediate focal infection of the middle ear; for, as already stated, there was a history of pain in the right ear for the first time after return home from the fever hospital, without, however, the further evidence of otorrhœa.

As René Benard [1] and others have emphasised, even though careful examination during life may fail to show any indication of involvement of the middle ear, frontal or sphenoidal sinuses, yet post-mortem examination may not uncommonly show unmistakable evidence of an otitis or sinusitis as a source of secondary meningeal infection in cases which might otherwise be regarded as primary meningitis and septicæmic in origin. Meningitis, when it occurs, is more often a late development, with onset about the period of desquamation, seldom as early as the fourth to eighth day of the fever. It has been described by the various observers as occurring on the fourteenth, twentieth, twenty-fourth, thirtieth and thirty-fifth, and even as late as the forty-fifth and fifty-fifth days.

* Read at a meeting of the Metropolitan Branch of the Society of Medical Officers of Health on Nov. 12th.

† It may be convenient to state that unofficial communications, such as this, from medical officers of the London County Council, must not be taken as expressing the views of the Council but only those of the individual officer.—ED. L.

In the case above recorded it may be noted that the first symptom of meningitis—headache—did not appear until the tenth week after the rash, and death followed 12 days later. The usual clinical course presents the classic picture of meningitis, with a duration described as ranging from one to eight or 16 days. Although Benard quotes a case recorded by Netter, in which recovery took place from streptococcal meningitis supervening on scarlatinal otitis, such an event is extremely rare, and the complication must be regarded as almost invariably fatal, unless prompt and effective operative measures are possible at an early date.

Previous Records of Scarlatinal Meningitis.

The records of meningitis complicating or following scarlet fever, even when secondary to an otitis media or sinusitis, are comparatively few, still more uncommon are the undoubted primary cases with no other focal lesion.

(1) *Observations in this Country.*—Dr. F. F. Caiger,[2] in his analysis of 1008 cases of scarlet fever in 1891, recorded complication by otitis media in 125, or 12·9 per cent., rhinitis in 58, or 6 per cent., but not one case of meningitis. In his later experience of the disease during the past 35 years Dr. Caiger writes that he could recall a few cases of scarlatinal otitis with mastoid suppuration, which terminated in meningitis, but only one in which meningitis was not secondary to middle-ear disease. I am also much indebted to Dr. E. W. Goodall for similar evidence of the rarity of a primary meningitis, supplied by his search into the post-mortem records of fatal scarlet fever for the past 30 years at the North-Western and Eastern Hospitals, which failed to show a single case of meningitis without otitis media as the cause of meningeal infection.

Reference is made by J. D. Rolleston,[3] in his text-book on "Acute Infectious Diseases" (1925), to the nervous phenomena not uncommonly met with in severe attacks of scarlet fever, and manifesting "some degree of meningeal reaction, shown clinically by slight nuchal rigidity, headache, and delirium, and on lumbar puncture by hypertension, with or without lymphocytosis of the cerebro-spinal fluid, which is clear and sterile. Suppurative meningitis is almost always secondary to otitis, rhinitis, or arthritis, but there are about eight cases on record of primary suppurative meningitis."

Also the late Claude B. Ker,[4] in his second edition of "Infectious Diseases" (1920), among the complications of scarlet fever, stated, "it is obvious that meningitis may occur in patients in whom the middle ear is seriously affected, and I have seen one fatal streptococcal case in which the ears were reported to be normal by an otologist."

(2) *Continental Records.*—The most complete account of meningitis complicating or following scarlet fever is to be found in the exhaustive paper by René Benard [1] (1909), who succeeded in collecting from statistics published in this country and on the continent a total of 13,550 cases of scarlet fever, among which only nine were reported as complicated by meningitis—i.e., less than 1 in 1500. He classified the available records of some 40 cases claimed to be scarlatinal meningitis into two groups: (1) Those published previous to 1900, in which meningitis was diagnosed mainly on clinical grounds from the exhibition of nervous phenomena in the course of an attack of scarlet fever. (2) Those reported after 1900, when, as the result of the introduction of lumbar puncture, it was possible to determine the nature of the meningeal reaction, whether constituting a true meningitis or not. Quite a proportion of the 40 collected cases he criticised as based on the insufficient evidence of clinical data only, without details of the cerebro-spinal fluid, or unsupported by post-mortem examination, and therefore open to doubt. Out of 28 authenticated cases of secondary meningitis, however, of which he found records, 14, or 50 per cent., were associated with otitis media, four with purulent rhinitis or coryza, two with suppurative arthritis, and in the remainder there was evidence of other focal infections such as frontal sinusitis, purulent ophthalmia, cellulitis, and pneumonia, occurring in the course of scarlet fever.

The probable paths of infection Benard maintained to be either by direct spread from the middle ear, mastoid or frontal sinus, or by transit through local lymphatics or blood capillaries, without necessarily visible continuity between inflammatory focus and meninges. Whereas a streptococcal invasion of the general circulation without focal infection was responsible for the much rarer condition of primary meningitis, there were also cases of secondary meningitis as the result of blood infection attributable to a distant streptococcal focus—e.g., scarlatinal arthritis. A sharp distinction was, therefore, drawn by Benard between primary and secondary meningitis, and as genuine cases of the former he accepted only those in which careful search during life and at post-mortem examination had failed to show any localised source of infection.

To the primary group undoubtedly belonged the eight cases collected or personally recorded by Teissier and Duvoir [5] in 1908, and more recently by them and Boudon [6] in 1922. As example may be cited one of Teissier's cases, of a youth, aged 20, who had an ordinary attack of scarlet fever, and on the eighteenth day (April 2nd) developed a rise of temperature to 40·4° C. with headache; later, insomnia, diarrhœa, and epileptic convulsions of Jacksonian type. On April 13th lumbar puncture yielded turbid purulent fluid showing many polymorphs and abundant long streptococcal chains. Death occurred on the following day, and post-mortem examination showed fibrinous purulent exudate over both vertex and base of the brain. The bones of the skull, mastoid, internal, and middle ear proved to be healthy.

Degrees of Meningeal Reaction in Scarlet Fever.

The above-mentioned writers also described cases of meningeal infection without cellular reaction, occurring as a transitory condition in the course of severe attacks of scarlet fever, from which recovery was possible; and Dr. Goodall has informed me that he has had very occasional experience of scarlatinal patients developing meningeal symptoms and recovering without other evidence of real meningitis. Although seldom met with, Benard drew attention to the same condition in his paper in 1909, and recognised varying degrees of meningeal reaction in response to the presence of the scarlatinal infective agent, whether a virus, whose nature is unknown, or a streptococcus or some other organism.

The character of the reaction lumbar puncture alone could determine, and thus assist in forming a prognosis. The following types were defined by Benard:—

1. Less severe and transitory states of meningismus associated with delirium, in which quite clear cerebro-spinal fluid was obtained in a state of hypertension to the amount of 35 c.cm. in 15 seconds, yielding no organisms and very few lymphocytes, or streptococci only, without evidence of cell reaction.

2. Those showing a more intense reaction—e.g., by a lymphocytosis of 80 cells per field and the presence of streptococci, as in a case recorded which recovered 35 days later. When such cases proved fatal, post-mortem examination showed no more than meningeal congestion and subpial hæmorrhages without evident meningitis.

3. Intermediate between the congestive meningeal reaction and the purulent form of meningitis was also recognised a sero-fibrinous pachy-meningitis with turbid gelatinous exudate composed chiefly of lymphocytes, distinct from:—

(4) The acute suppurative meningitis yielding turbid fluid with deposit of pus cells and streptococci in films and culture, and showing a more or less thick layer of pus in the meninges of both vertex and base, to which more usual type the case here recorded probably belonged.

My thanks are due to Dr. Caiger and Dr. W. MacCormac for kindly providing the clinical notes of the patient when at the South-Western and St. James's Hospitals, also to Dr. Caiger and Dr. Goodall for the benefit of their unrivalled experience of scarlet fever, and to Dr. F. Griffith for determining the type of streptococcus isolated from the cerebro-spinal fluid.

THE LATE DR. J. F. GEMMEL.—Dr. James Francis Gemmel, who died on Nov. 22nd at Joppa, near Edinburgh, was the eldest son of the late Dr. James Gemmel, of Dunoon, Argyllshire, and graduated in medicine at the University of Glasgow in 1883. After acting as house physician in the Glasgow Royal Infirmary, he became senior assistant medical officer of the county asylum, Lancaster, and later was appointed medical superintendent of the county asylum, Whittingham. On retiring from this post a few years ago he went to live in Edinburgh.

A CONGENITAL CASE OF KALA-AZAR.

BY GEORGE C. LOW, M.D. EDIN., F.R.C.P. LOND.,
SENIOR PHYSICIAN, HOSPITAL FOR TROPICAL DISEASES, LONDON, AND SEAMEN'S HOSPITAL, ROYAL ALBERT DOCKS, E.;
AND
W. E. COOKE, F.R.C.S. IREL., D.P.H.,
MED. SUPT., HOSPITAL FOR TROPICAL DISEASES.

So far as we are aware no case of congenital kala-azar has ever been described in the literature of this disease. It is possible that such cases have occurred in India, but in an endemic area this is difficult, if not impossible, to prove.

Recently we have had the unique experience of seeing a case of an infant, born in England, of a mother suffering from kala-azar, which disease subsequently developed in the child. Before being able to say definitely that an infection is really congenital—e.g., occurring through the placenta—sources of possible fallacy have to be rigidly excluded. We believe that, in this individual case, all such sources have been eliminated.

History of Mother's Case.

Mrs. A., 33; born Isle of Man, lived in United Kingdom till 1916, when she married and went to India. She remained there—except for leaves home—living at various stations, until *June, 1925*, when she came to England, where she has resided since.

Previous Illnesses.—Measles, bronchitis, influenza, malaria in 1916, dengue September, 1924; no other illnesses.

Present Illness.—After her attack of dengue, which was acquired in Calcutta where she was living at the time, patient went to the hills near Darjeeling for a month. From there she returned to Calcutta to her home in Alipore and resumed her normal life. At Christmas, 1924, she got a cold, did not feel well, and noticed about this time that she was pregnant. Her ill-health continued, but she attributed this to the pregnancy. In March, 1925, she noticed a rise of temperature every evening to 100° or 101° F., and, on consulting a doctor, a heavy growth of *Bacillus coli* with much pus was found in her urine. Vaccine treatment and alkalis were given, the urine cleared, but the temperature remained above normal and her general condition got worse. Blood examinations were negative for malaria, and the serum did not agglutinate any of the typhoid group. A blood count showed her white corpuscles only to be 2000 and her spleen was found to be enlarged, three-quarters of an inch below the costal margin. She then consulted Dr. Napier, who cultivated her blood for leishmania with negative results. No splenic puncture was made. She was then given quinine for seven days to see if this would have any effect upon her temperature, but as this failed entirely to influence the pyrexia, and as her condition was rapidly becoming grave she was given urea stibamine intravenously. In all five injections of this were given (0·4 g. in toto), and then, the temperature having subsided and the symptoms having greatly improved, she was sent home to England, where she arrived on June 10th, 1925. She went into a nursing home in Manchester 14 days after arrival as the symptoms had recurred, and there she was given three further intravenous injections of urea stibamine. Improvement again took place and she left the nursing home. She returned there later for her confinement and her child was born on *Sept. 12th, 1925*. After this she began to fail in health again, fever recurred, and eight weeks after the confinement the condition became alarming. She was then sent to the Hospital for Tropical Diseases where she came under our care on *Nov. 6th, 1925*.

Condition on Admission.—Patient was very ill. There had been considerable loss of weight, a high remitting fever was present, and the abdomen was filled with a large spleen coming down four inches below the left costal margin. A blood count showed red cells 2,600,000, white cells 1800, hæmoglobin 60 per cent. There was considerable poikilocytosis; no nucleated red blood corpuscles were seen, and no malarial parasites. As the heart sounds were very feeble and the pulse weak and irregular, strophanthus was prescribed. As there was no doubt as to the diagnosis, no splenic or liver puncture was made. On Nov. 9th stibosan (von Heyden "471") was commenced in doses of 0·1 g. intravenously, this being increased at the next injection to 0·2 g. and then continued at this dose every third day. Response was good, the temperature being lower at the end of the first week and then gradually settling to practically normal in the third week. The general condition also improved; the spleen went down and she began to put on weight. Four grammes of stibosan, in toto, were administered, and the patient left the hospital to all intents and purposes cured on Feb. 2nd, 1926.

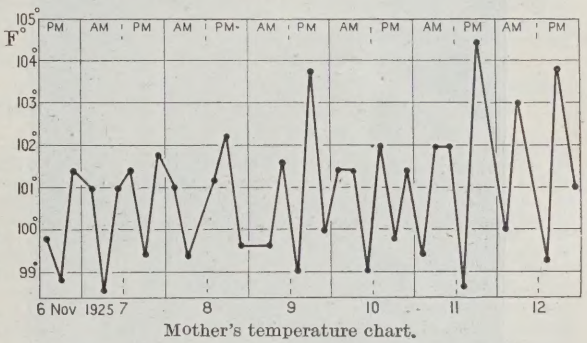
History of Pregnancies.—Children two, the first baby being born in England before she went to India She became pregnant for the second time in India in December, 1925 (last menstrual period Nov. 28th), and went on to full term, the child—the one under discussion—being born in Manchester on Sept. 12th, 1925. Though suffering from kala-azar all the time, the pregnancy went on normally and no untoward symptoms appeared. No history of miscarriages or premature births or anything of gynæcological interest could be elicited in her case.

History of the Child's Case.

F. C. A., male. Weight at birth 7 lb. Confinement normal, no instruments used, slight tear of perineum necessitating two stitches. Never suckled or nursed by mother, but kept in room apart in nursing home, and subsequently taken care of by a nurse of its own for the two months before mother came into hospital, as she was too ill to look after it herself. For the first fortnight after birth did well, and then had a convulsion and was poorly for a week and never picked up properly after that. About seven weeks later started with bad diarrhœa and pain, and was then put into a nursing home in Exeter, where the mother was then staying, under Dr. C. E. Stokes.

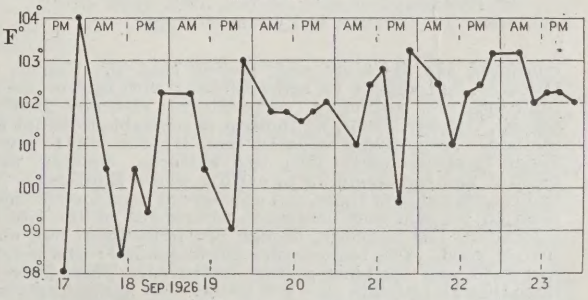
It was at this time that the symptoms of the disease recurred in the mother and she left the baby and came up to the Hospital for Tropical Diseases as described above. On leaving hospital on Feb. 2nd, 1926, the mother asked if there could be any chance of the baby acquiring the disease, and we reassured her that we had never heard of such a case and that there was little cause for worry. However, we suggested that she should bring the infant up for an examination, and this was done in March, 1926. The baby then did not look very strong and had rather a pasty appearance, but as there was no enlargement of the spleen specially noted, we just told the mother to let us know if any further developments took place.

FIG. 1.



Mother's temperature chart.

FIG. 1A.



Baby's temperature chart.

During the summer of 1926 the mother noted that the child was not well, but as some teeth were coming at the time, she thought the clinical symptoms were due to these. Towards the end of August no improvement having taken place and, as the abdomen was now becoming very prominent, the mother became alarmed and finally brought the child up to London to us for another examination on Sept. 17th, 1926.

Examination.—A glance practically showed the diagnosis. There was marked anæmia, emaciation, and a protuberant

abdomen, due to an enormously enlarged spleen well down below the umbilicus. In addition to this there was a high temperature of a remitting nature. The blood count was as follows: R.B.C., 1,600,000; W.B.C., 2600; hæmoglobin, 30 per cent.; poikilocytosis and nucleated red cells.

We got Dr. C. M. Wenyon to see the case, and on Sept. 20th one of us (G. C. L.) put a needle into the spleen and aspirated some of the juice. Smears made from this revealed quite numerous Leishman-Donovan bodies. The diagnosis made clinically was thus confirmed microscopically and it was evident that the child had kala-azar.

Treatment.—The difficulty and risk of giving such a debilitated infant of this immature age intravenous injections of antimony had to be faced. In view of this we consulted the literature and, finding that Dr. Napier, of Calcutta, had written an article dealing with intramuscular injections of antimony preparations (*Indian Medical Gazette*, October, 1925), we thought it advisable to adopt his method. Accordingly stibosan (von Heyden "471") was given intramuscularly into the buttocks, starting with 0·025 g. and increasing up to 0·075 g. every third day. No bad results followed these, and only on one occasion did there seem to be pain and tenderness afterwards at the site of injection. The response, though not immediate, was ultimately good. The temperature fell to normal; the weight increased, and the blood picture improved. There is every hope that an ultimate cure will result. We propose giving, following Dr. Napier again, 1 g. or even up to 1·59 g. in toto.

FIG. 2.

Photograph of baby on Oct. 19th, 1926, after having had 0·7 g. stibosan.

Discussion as to Mode of Infection of Child.

1. In the transmission of kala-azar an infected person appears to be essential. 2. There is strong evidence that the disease cannot be spread without the aid of an intermediate host, which is probably a blood-feeder, most probably of the genus *Phlebotomus*, or the genus *Culicoides*, and recently considerable evidence has been advanced that a sandfly, *Phlebotomus argentipes*, is the transmitter of the causative organism. Other insects such as fleas, lice, bugs, ticks, mites, and mosquitoes have all been suspected without much supporting evidence. 3. The preponderating mass of evidence is incompatible with the suggestion that the disease can be spread directly from man to man, or even indirectly by such media as water and milk, &c., while there is an increasing improbability that infection can follow ingestion of the parsasite.

Bearing these facts in mind many questions that arise in the case under discussion can be answered. The source of the child's infection, occurring as it did in England, was undoubtedly the mother. The question of the intermediate host can also appear to be eliminated. At the confinement, conducted in a nursing home with a doctor and trained nurse present, ordinary precautions would be observed. The subsequent care of the child in a separate room, with a nurse of its own, and only occasionally in the presence of its mother, owing to her weak condition—both in the home at Manchester and for the short period subsequently before the mother came to the Hospital for Tropical Diseases—and living as they were under ordinary English conditions, rules the possibility of an intermediate host out.

Other Means of Infection at the Birth.—Infection by intestinal discharges; Mackie has been unable to demonstrate such a path of infection, and it is not supported in the report of the Kala-azar Commission, India, 1924–25. Besides, with a properly conducted labour, as this one was, this should be entirely obviated. As regards any possibility of infection during the second and third stages of labour, it may be noted that the mother had slight leucorrhœa for the last few weeks of pregnancy. The labour was normal, no instrumental interference being required, but the perineum subsequently had to be stitched. There were no abrasions upon the body of the child and the cord was tied in the usual way between double ligatures. While admitting the outside possibility of infection during this short period from the perineal hæmorrhage—if this actually did occur—or from the leucorrhœa, the ascertained evidence appears all against such a happening. There were no signs macroscopically of disease in the placenta, but unfortunately the organ was not kept. The mother did not suckle the child, so this avenue of infection can be excluded, and though she kissed the baby occasionally there is no evidence that this can transmit the disease; it is most improbable that it should. The probability of infection from association with the mother after her return from the Hospital for Tropical Diseases can be ignored, because the mother left the institution apparently cured and has remained in perfectly good health since, with no signs of any return of the malady.

The period that elapsed from birth before the appearance of symptoms in the infant is not incompatible with a placental infection. It is just possible that the injections of urea stibamine, given to the mother while she was carrying the fœtus, may have been beneficial to the latter. When the symptoms really did appear after the birth is uncertain. The incubation time for kala-azar is not definitely known, but periods of 10 or 12 months before symptoms become marked are not unusual.

Taking all these facts into consideration, it would appear that in this case the disease was congenital—i.e., conveyed through the placenta. This is very interesting as *Leishmania donovani* is chiefly a cellular parasite. It is however found in the blood stream in the leucocytes, and this is how the intermediate host must acquire the infection. As the blood in the placental vessels is only separated from the maternal blood by a thin intervening membrane the infecting parasites must have passed into the fœtal circulation in this way and so infected the infant.

In view of the extreme interest of this case we should like to suggest to practitioners in India that, if they have similar cases of kala-azar mothers being pregnant, the placenta be submitted for careful microscopical observations. It is quite possible that congenital infection of kala-azar is a not uncommon occurrence in the endemic areas of the disease.

Note.—Just as our paper was going to press Mrs. A., the mother, complained of feeling slightly feverish at night, so we re-examined her and, finding that the spleen had increased in size and that the leucocytes had

gone down in numbers, we thought it advisable to do a splenic puncture. This was positive, plenty of Leishman-Donovan bodies being present in the film. The mother has therefore relapsed. This, then, raises again the question of the possibility of direct contact infection of the child from the mother, but as already stated, all the evidence is against the possibility of such a mode of infection.

ULTRA-VIOLET RADIATION.

SOME ILLUSTRATIVE CASES.

BY A. LISLE PUNCH, M.B., M.R.C.P. LOND.,
PHYSICIAN, BROMPTON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST; PHYSICIAN, ROYAL NORTHERN HOSPITAL;
AND
RUSSELL WILKINSON, M.V.O., M.R.C.S. ENG.,
PHYSICIAN TO H.R.H. THE PRINCESS ROYAL.

THE therapeutic value of ultra-violet radiation is now so firmly established that a mere record of cases which have benefited by it does not justify publication. A study of the seven cases dealt with in this communication, however, reveals certain special points in the administration of ultra-violet light and constitutes our justification for recording the cases. Cases 1 and 2 would appear to us to offer evidence of the value of local combined with general treatment. How the local application acts it is difficult to understand, but the whole question of the manner in which ultra-violet radiation brings about its beneficial results in suitable cases is at present a matter of conjecture. The penetrative powers of the rays of the Kromayer lamp are very slight, and, although bactericidal to some extent, their action in this respect is so superficial that it can hardly be by such means that they produce their therapeutic effect.

From an experience of a large number of cases, of which Cases 1 and 2 are examples, there appears to us very little doubt that local treatment, when combined with general exposure, plays a very important part in the relief of certain conditions. Case 4 is chiefly of interest in that the symptoms of a condition of a very obscure nature were considerably relieved by ultra-violet radiation. The treatment was entirely empirical, but, where diagnosis is doubtful, treatment must of necessity be empirical.

Clinical Records.

CASE 1.—Male, aged 51, suffering from widespread genital tuberculosis, involving the epididymides, prostate, and vesicles. A prostatic abscess developed, which threatened to burst into the rectum. Mr. J. Alban Andrews evacuated the abscess and removed the remains of the tuberculous prostate by dissection. In July, 1925, a bilateral epididymectomy was performed. A month later the patient was discharged from hospital. His general condition was good, but urine was leaking from a persistent suprapubic fistula, which was to be repaired later.

The patient was readmitted in October, 1925, the fistula was excised, and the abdominal wall repaired. The great amount of perivesical scar tissue rendered mobilisation of the bladder difficult, so that the space immediately behind the symphysis pubis could not be completely obliterated. This was drained. Three days later an abscess developed and discharged through the lower end of the suprapubic wound. Again a suprapubic fistula was established, although there was no urethral obstruction. Urine contained pus in large amounts.

When first seen on Dec. 10th, 1925, both seminal vesicles were hard and clinically tuberculous. There were two suprapubic fistulæ, from which urine leaked. They were surrounded by dense scar tissue, and the lower one was depressed below the surface. Over these the patient was wearing pads of wool, which had frequently to be changed, and there had been no alteration as regards this since the operation.

Treatment by ultra-violet radiation was begun on Dec. 10th, 1925, daily at first, and, later, with a few days interval. General treatment by the mercury-vapour air-cooled lamp was given on the first nine occasions, with exposures varying from 2 to 20 minutes at a distance of 36 inches. Local treatment was given by means of the Kromayer water-cooled lamp, short contact exposures being made with a quartz rod or quartz lens to the fistulæ. In all, 28 treatments were given over a period of 13 weeks, the later general treatments alternating between the air-cooled mercury-vapour lamp and the long flame carbon arc lamp. From time to time local treatment was given to the whole area of scar tissue by the tungsten arc lamp.

The fistulæ have now closed, the patient has put on over a stone in weight, and has returned to his work as a blacksmith. It was found necessary from time to time to give local treatment, as, if this was suspended, there was a tendency for the condition to become stationary. After each local treatment there was a definite diminution in leakage after a temporary increase lasting about 24 hours.

This case seems to demonstrate clearly that the local treatment played a very important part in the cure.

CASE 2.—Male, aged 45. Had a chronic discharging fistula of the thorax for three years, the result of an empyema following pneumonia in 1923. Occasionally the discharge ceased for a day or two, but always returned. Three operations had been performed with the object of closing the sinus, but without success.

When referred to us the patient had a sinus at the level of the eighth rib. From this sinus there was a profuse discharge of foul-smelling pus. The patient's general condition was poor and his appearance "septic."

Examination of chest showed impaired percussion note with diminished voice conduction, and weak breath sounds over the base of left lung.

Treatment began on March 23rd, 1926. Twenty exposures were given to the mercury-vapour air-cooled lamp and the long flame carbon arc lamp. In addition, local treatment with the Kromayer lamp was given to the chest wall in the region of the sinus, the rays being conducted along the sinus by means of a fine quartz rod inserted therein. An intense local reaction was aimed at and produced. The discharge ceased after five treatments and the sinus healed rapidly. There was also definite improvement in the general condition. Treatment continued at intervals until May 25th, 1926. A subsequent X ray examination showed evidence of thickened pleura, but no fluid in chest.

The sinus is now closed and completely healed. There has been no discharge for over six months.

CASE 3.—Male, aged 26. Hodgkin's disease. In January, 1924, patient complained of general weakness and loss of weight, and an enlarged gland was found in the left axilla and old shotty glands on both sides of neck. He went to Leysin under Dr. Rollier for the remainder of that winter. In July, 1924, some tender glands were observed on left side of neck. A white cell count showed a leucocytosis of 18,000 with 3 per cent. of eosinophils. Later, the white count increased to 20,300. No pyrexia. The following winter was again spent at Leysin, and on his return in June, 1925, a gland was removed which microscopically revealed changes typical of Hodgkin's disease. At this date another group of glands had arisen on the right side of neck. These visits to Leysin had benefited him very considerably. In November, 1925, it was decided that instead of going to Leysin, the patient should have a course of ultra-violet radiation.

At this time enlarged glands could be felt on right side of neck, axilla, both groins, and one in the right iliac fossa. Spleen and liver not felt. Mucous membranes pale. Patient complained of feeling "run down." Blood count was as follows: red cells, 4,400,000; white cells, 21,000; hæmoglobin, 81 per cent.; colour-index, 0·9. Differential count (per cent.): polymorphs, 77·66; lymphocytes, 5·66; large mononuclears, 7·0; eosinophils, 9·0; basophils, 0·66; so that the picture was one of a slight degree of secondary anæmia with a considerable leucocytosis and marked eosinophilia. Treatment was begun on Nov. 20th, 1925. In all, 19 treatments were given with either the mercury-vapour air-cooled lamp or the carbon arc lamp, with exposures starting at five minutes and increasing up to 25 minutes at 36 inches distance.

Blood counts were done as follows:

Further blood counts.	28/11/25.	6/12/25.	2/1/26.
Red cells	4,400,000	4,500,000	4,640,000
White cells ..	13,000	14,640	10,430
Hæmoglobin ..	86%	91%	91%
Colour-index ..	0·97	1·0	1·0

Differential count (per cent.) on Jan. 2nd, 1926: polymorphs, 79·5; lymphocytes, 11·0; large mononuclears, 6·0; eosinophils, 2·5; basophils, 1·0.

Even allowing for the well-known fluctuations that occur in this disease, especially as regards the white cells, it would appear that there was an improvement in the blood condition

during treatment. There was a definite rise in the hæmoglobin content, and an even more definite drop in the white cell count and in the percentage of eosinophils, so that the actual number of eosinophils circulating in the blood was very markedly decreased. During the treatment the enlarged glands diminished in size and no fresh enlargement of glands appeared. The temperature taken before and after each exposure showed no pyrexia throughout. The patient himself stated that he felt much benefited, and that the effect on his subjective symptoms was comparable with that experienced on his previous visits to Leysin.

The results in this case would suggest that the artificial, no less than the natural, sunlight has a therapeutic value in alleviating the symptoms and retarding the progress of Hodgkin's disease.

CASE 4.—Male, aged 27. A case of an obscure character which appeared to be an arteritis of some sort. He complained of pain and swelling in the toes and foot on the left side, and inability to place the foot flat on the ground without discomfort, so that he walked on the outer side of the foot. On inspection the toes and foot were observed to be somewhat swollen, cold, and cyanosed. Movements of all joints full and free. Seven years previously a similar condition was present in the other leg, and the right calf now measured half an inch less than the left, owing to subsequent wasting of the muscles on the right side. Wassermann reaction was negative.

Treatment by ultra-violet radiation was begun on Jan. 25th, 1926, and consisted in general baths with the mercury-vapour air-cooled lamp and carbon arc lamp, with local treatment to the foot with the former. Fourteen general and six local treatments were given over a period of four weeks, at the end of which time the coldness, swelling, and cyanosis of the foot had disappeared. The patient was able to put the foot flat on the ground without discomfort, and the pain which prior to treatment had been severe, especially first thing in the morning, was no longer present.

CASE 5.—Male, aged 36. Severe acne of chest, abdomen, and back of 20 years' standing. General baths with the mercury-vapour air-cooled lamp and carbon arc lamp were given, and after ten exposures the condition had almost completely cleared up with the exception of a few larger pustules, to which it was necessary to apply the Kromayer lamp with a quartz rod on two subsequent occasions.

CASE 6.—Severe acne of the face in a girl aged 16. General exposures were given as in the previous case, and local treatment was also given to the face with the tungsten arc lamp and the Kromayer lamp to individual pustules. For the first 10 or 15 treatments very little improvement was observed, but later this became definite, though slow. In all, 35 treatments were given, and at the end of this time the skin was clear and the scars of previous pustules scarcely noticeable.

Cases 5 and 6 were examples of severe degrees of acne. In our experience, ultra-violet radiation is of the greatest value in the treatment of this condition. There is considerable variation, however, in the readiness with which such cases respond to it. The first case was an example of a large group in which the response is almost immediate and in which the condition clears up very rapidly; the latter was an example of a smaller group in which the condition is refractory and requires prolonged treatment, but the results are ultimately good.

CASE 7.—Female, single, aged 32. Debilitated, pale, and listless. Bouts of indigestion of colonic type. Anorexia nervosa. Catamenia absent for ten months.

Treatment began March 26th, 1926, with general exposures, and was continued until 17 had been given up to May 3rd. On March 29th a scanty flow started, rusty in appearance, lasting four days. On April 5th a flow began lasting five days, and of a more normal appearance and quantity. On April 27th a six days' flow, practically normal. Treatment was suspended from May 3rd to May 17th, when three more exposures were given before the period was due. The period began on May 28th, lasted seven days, and was quite normal There is no indigestion, appetite is normal, and all subjective symptoms have disappeared.

This re-establishment of menstrual function, erratic at first but becoming normal in eight weeks after a complete cessation for ten months, seems to justify the treatment of functional abnormalities of ovarian or uterine activity by ultra-violet radiation.

We wish to record our indebtedness to Sir Thomas Horder and Mr. J. Alban Andrews for permission to publish accounts of those of the above cases which they sent to us for inclusion in this paper.

VENTRICULAR PUNCTURE IN APOPLEXY,

WITH REMARKS ON THE TECHNIQUE AND USES OF THE OPERATION.

BY HILDRED CARLILL, M.D. CAMB., M.R.C.P. LOND.,

PHYSICIAN TO WESTMINSTER HOSPITAL AND WEST END HOSPITAL FOR NERVOUS DISEASES.

As a cerebral hæmorrhage of any but the smallest magnitude is a fatal condition, any method of attack which offers a prospect of relief is worth trial. The following brief preliminary note is of a procedure in apoplexy which I have not seen described.

A Case Related.

A man, aged 50, suffered from headache for a few hours. At 2 P.M. on Jan. 8th, 1926, he was taken ill suddenly at his work and was admitted forthwith to Westminster Hospital. He remained conscious until 4 P.M., vomiting several times. When I saw him at 5 P.M. he was unconscious, and showed a complete left-sided flaccid hemiplegia. The right upper limb was in active movement, the man pressing his hand against the right side of his head. The eyes squinted divergently. The pupils were small and inactive to light. The tendon jerks were exaggerated bilaterally, and there was clonus at both ankles. The left plantar response was extensor in type, the right flexor. The clinical diagnosis of apoplexy was confirmed by immediate lumbar puncture, which showed the cerebro-spinal fluid intimately mixed with blood, but not under an excessive pressure. The pulse-rate was 80 per minute. We considered that the hæmorrhage had already passed across from the right to the left side of the brain.

At 6 P.M., with the assistance of my house physician, Dr. H. A. Dunlop, I punctured the right lateral cerebral ventricle by means of a drill and needle. Hæmorrhagic cerebro-spinal fluid at once escaped, but the flow was slow. When the patient's head was allowed to fall downwards and backwards over the end of the bed, the flow—by gravity—was at once somewhat increased, and a still better flow was obtained by digital compression of the jugular veins. The patient vomited frequently, and there was copious double incontinence. A small syringe, used gently, was filled several times by suction of the ventricular contents. About 10 c.cm. were withdrawn. At 7 P.M. the pulse-rate was 60. The condition of the pupils and reflexes was unchanged, and although there was now more profound unconsciousness, the man's right hand was as before passed frequently to the right side of his head. The operation was successfully performed, but the result was negligible. Death occurred at 1 A.M. At the autopsy Dr. Braxton Hicks was unable to assign any special cause for the hæmorrhage. The heart, kidneys and arteries, general and cerebral, were healthy for the age of the patient. The right ventricle was occupied by an extensive clotted hæmorrhage which had destroyed the brain and which had passed in part into the left ventricle and, as has already been indicated, into the smaller ventricles and spinal subarachnoid space. The spot where the needle had pierced the brain en route to the ventricle was adjacent to a large cortical blood-vessel.

Technique of Puncture.

My knowledge of the operation of ventricular puncture in adults has been obtained chiefly from my colleague, Sir James Purves-Stewart (see his paper in THE LANCET, Dec. 5th, 1925). I have performed it a dozen times. I have found, however, that for a right-handed operator an ordinary right-handed multiplying action drill, with a handle on the left side and with a corkscrew groove in the drill, is quite satisfactory. If a very small puncture wound is desired, as usually is the case, the drill should be the smallest which is larger than the fine lumbar puncture needle to be used. The only difficulty with the drill I describe is that of finding the bony tunnel with the needle after the drill has been withdrawn, but, if a skilled assistant keeps the scalp firmly fixed to the skull, this is inconsiderable. When an area of the scalp had been properly shaved and carefully washed, the site of the proposed puncture, in the case of a conscious patient, is sprayed with ethyl chloride. The operative risk of septic meningitis is a definite one. When the operation is completed, a wooden match, whittled down and carrying pure carbolic acid, is inserted into the wound for a moment. I have the match ready at the outset for possible use as a plug

in case of bleeding from the bone, but I have not had occasion to make use of it. It does not appear to matter if by mischance the drill point is apparently carried by the weight of the body through the dura mater, but the risk of cortical hæmorrhage must be considerable in such an event. Perhaps the dura mater is pushed in front of the drill point. Whether the meninges are pierced or displaced, the conscious patient feels no pain at this or any time. None of my patients have had either pain or shock, immediate or later on. They may hear the movement of the drill unless their ears have been plugged, but they feel nothing unpleasant. They make neither sound nor movement. In the case of a man suffering from severe acromegaly, notably of the skull, the operation was completed and the cerebro-spinal fluid withdrawn before he appreciated that it had commenced. In addition to the risk of meningitis, a definite danger of ventricle puncture is perforation of a blood-vessel lying on the surface of the brain. I have heard of a case in which extensive subarachnoid cerebral hæmorrhage occurred from this accident, and it appears that neither anatomical knowledge nor operative skill can prevent it in a proportion of cases. Our safeguard is to be certain that the drill point passes no further than through the inner table, and to be certain also that the needle point is guarded accurately by its stilette until it has passed, at any rate, beyond the surface of the brain. But, operating by touch alone, it is not easy to be certain of these things. In some cases, especially when one or both ventricles have been displaced laterally, it may be the contra-lateral ventricle which is penetrated by the needle.

Results of Puncture.

The relief of headache, afforded by ventricular puncture to a patient with internal hydrocephalus, from whatever cause, is dramatic. In cases of apoplexy the pain which often is demonstrably present on the side of the head where the bleeding is taking place, may be due to the result of internal hydrocephalus. To some extent any increase of subarachnoid pressure in apoplexy may be lessened by withdrawing the bloody cerebro-spinal fluid from the cistern or lumbar region. Unconsciousness in apoplexy is caused no doubt in the main by destruction of the brain by the pressure of the collection of blood. Whether unconsciousness can be prevented or relieved by ventricular puncture at a very early stage of the hæmorrhage, remains to be proved. I know that during life blood within the cerebral and spinal subarachnoid spaces may clot, but I do not know whether blood within the ventricles during life clots rapidly or slowly, or if it clots there during life at all. Perhaps aspiration of the fluid contents of the ventricle would encourage the ruptured vessel to bleed more than ever, but the escape of the blood by gravity through the ventricular puncture needle might be beneficial. Perhaps also, in an early stage of bleeding, the affected ventricle might with advantage be gently filled with hæmostatic serum introduced through the ventricular needle, the subarachnoid pressure being controlled, if thought necessary, by simultaneous cistern or lumbar puncture, or both. With a needle of wide bore, venepuncture may be performed at the same time for the purpose of reducing blood pressure. A possible difficulty in introducing serum with the technique I describe, might be that of keeping the needle point stationary in its longitudinal axis within the ventricle during the fixing of syringe or tubing.

The clinical diagnosis of suspected apoplexy may be proved in most cases by the visible examination of cerebro-spinal fluid withdrawn by whatever route. Therapeutics apart, diagnosis depends on this ready proof and demands it. The diagnostic difficulties between supposed cerebral hæmorrhage and coma from—e.g., suspected opium poisoning, of which we hear the accounts, would no longer occur if this method of proof were universally practised. Some years ago, during a ward round, a man whom I had just described as a likely candidate for a cerebral hæmorrhage became suddenly unconscious while I was at another bed-side in his ward. Lumbar puncture within the first two minutes withdrew a colourless cerebro-spinal fluid. Lumbar puncture five minutes later revealed the hæmorrhage and clinched the clinical diagnosis.

The cistern route is now frequently employed for therapeutic and diagnostic injection, and for the relief of headache in cases of cervical subarachnoid block; and in several cases of meningitis I have washed the spinal subarachnoid space from the lumbar sac to the cistern. I have not yet injected antisera, syphilitic or otherwise, by the ventricular route. I have had one case, however, in which we demonstrated the use of ventricular puncture in affording an exit for fluid during lavage of the spinal and cerebral subarachnoid space conducted from the lumbar region. The patient was admitted with suppurative meningitis, which had developed apparently from infected skull sinuses. Lavage with saline was employed as described. The purulent fluid, which escaped slowly from the ventricular needle, became gradually colourless during the operation. The lavage did no harm, from the clinical point of view at any rate, but death occurred in due course from the meningitis. Autopsy showed that the convex surface of the brain on the side subjected to ventricular puncture was free from visible meningitis. The opposite cortex, on the other hand, was covered with purulent exudate.

Clinical and Laboratory Notes.

A CASE ILLUSTRATING THE AFTER-EFFECTS OF POISON GAS.

BY THOMAS NELSON, B.M. OXF., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO ST. GEORGE'S HOSPITAL AND TO THE BROMPTON HOSPITAL.

THE immediate action on the lungs of poison gases, especially chlorine and phosgene, has been studied close to the field of battle, but the after-effects of this weapon are only vaguely known. Though many ex-soldiers have died, post-mortem examinations have been made relatively seldom. The records of the following case are incomplete, because, through a misunderstanding, the lungs were not kept for microscopic examination; but the macroscopic appearances were so definite as to justify publication. For the previous history of the case I am indebted to the Director-General of Medical Services, Ministry of Pensions, and to the Board of Pension Commissioners of Canada, both of whom have placed all their available information at my disposal.

Clinical History.

The patient, a Canadian, was gassed at St. Julien about April 23rd, 1915, during one of the first gas attacks in the second battle of Ypres, so that his condition was probably due to pure chlorine. He developed a bad cough and frothy sputum, but did not go sick till May 24th, after a second gassing at Festubert. He was rapidly transferred to Le Havre and thence to England. At this time he had a great feeling of distress about the throat and left chest, with dyspnœa, severe cough, and copious sputum. A month later the eyes were still very engorged, the cough had nearly ceased, the area of cardiac dullness was decreased, and there was poor chest expansion and air entry, especially on the left side, with a few rhonchi. The note was made: "Probably some old broncho-pneumonic condition left side," and he was described as looking 30, although 41 years of age.

By Sept. 16th his condition and personal comfort had very much improved, though there were rhonchi and shortness of breath. A medical board, in October, 1915, found: "Small expansion of lungs, breathlessness on exertion with pains over chest; some parts show large dry râles and other parts intensified breath sounds. Has been steadily losing flesh." Otherwise their extensive examinations (of urine, blood, &c.) were negative. The board recommended his discharge as permanently unfit, and on his return to Canada

another board discovered "suspicious signs of softening at right apex," gave him a 50 per cent. disability pension, and sent him for observation. No evidence of tuberculosis was found.

There is no record until 1917, when he had apparently returned to England. He was then described as very short of breath, and the word asthma was used. He was thereafter examined every year in London and noted as having chronic bronchitis and emphysema with steadily increasing shortness of breath. About 1921 he appears to have first mentioned general nervousness, and a neurological board found a mild degree of anxiety neurosis. Apparently he never saw a special *medical* board, but in 1924 he was sent to the tuberculosis officer of a reputable London chest hospital, who found bronchitis with no evidence of tuberculosis. In 1925, at the same hospital, an acting tuberculosis officer found "pulmonary tuberculosis, slowly active," and this put his assessment up to a much higher level—not, I should think, unjustly. Subsequent boards, and another tuberculosis officer, recorded their inability to find tuberculosis, but the diagnosis stuck and did more good than harm.

A board in February, 1926, made a statement to this effect: "Weight 109 lb. (120 lb. on enlistment). A barrel-shaped chest, marked bronchitis all over. Pensioner states œdema at times, none now. Pulse 90, with poor exercise tolerance." They gave him 80 per cent. of disability and could find no sign of tuberculosis.

Recent Condition and Findings at Autopsy.

He was admitted to St. George's Hospital in April, 1926, and was then a cyanosed man, looking several years more than his age, with marked œdema of both legs and the left arm, and slight clubbing of the fingers. The apex of the heart was one inch outside the nipple line and the beat was very irregular with numerous extrasystoles. His blood pressure was 140–190, and his vital capacity 63 per cent. below normal. He had a round emphysematous chest with poor but equal expansion. There was dullness over the lower half of the right lung behind, with rhonchi and sibili all over both lungs—so loud and persistent that it was impossible to describe his breath sounds. Urine was very scanty with a fair amount of protein. The deposit contained red cells, pus, and granular casts. No organism was found in the urine nor any tubercle bacilli in the sputum. The Wassermann reaction was negative.

After a week in hospital the amount of urine had increased to about 40 oz. per day, and it contained nothing abnormal; after a month he was greatly improved in every way, and was getting up and about. His chest was nearly clear of rhonchi, except at the right base where the dullness with loss of vocal resonance persisted. His heart was normal in size, but still showed an occasional extrasystole.

On June 3rd, however, he complained of pain in the left side and his temperature rose to 102° F. The next day the classical signs of broncho-pneumonia were present in the left lower lobe. He became very feeble, blue, and dyspnœic, and on June 8th complained of pain in the right side, though no certain signs beyond numerous moist râles mixed with the rhonchi were discernible. The next day he died rather suddenly in a fit of dyspnœa.

Post-mortem Examination.—All the organs appeared normal except the heart, which was flabby and friable, but without gross organic lesion; the kidneys, which were unusually flabby, but otherwise normal; the liver, which was congested; and the lungs. The left lung showed confluent broncho-pneumonia, mostly in the lower lobe. The whole lung, and especially the lower half, was much more waterlogged than is usual in broncho-pneumonia. The pleura over the right lower lobe was very much thickened, and within the lobe were many small bronchiectatic cavities, the largest of which would have contained a hazel nut. The lung was by no means "honeycomb," and the cavities were separated by rather hard, congested lung tissue, with broncho-pneumonic patches. The whole lobe was waterlogged and there was a confluent broncho-pneumonia in the middle lobe. Both upper lobes were congested, but not grossly diseased. There was no evidence of tuberculosis.

Discussion.

The man had no history of any previous disease. Taken together with the note by one of his early boards that he looked younger than his age, this makes it quite certain that the patchy bronchiectasis of one lobe must be attributed to lesions in the bronchi caused by the direct action of chlorine on them. The conclusion cannot be avoided that the intense inflammation of the whole respiratory tract following gassing, if it does clear up quickly enough to prevent the immediate death of the patient, may leave behind it a partial necrosis of the bronchial walls. These soft and weakened structures gradually dilate in the course of years. They form foci for the general pathogenic organisms of the lungs, and these cause more and more general bronchitis. Thus a vicious circle is formed, as the coughing tends more and more to dilate the bronchi.

The original lesion as noted a few weeks after his gassing pointed to the left side being chiefly affected; it was regarded as "possibly some old broncho-pneumonic condition." The patient's fatal broncho-pneumonia started on this side, and this may or may not have been accidental. The thickened pleura over the cavity area is rather curious, and it is still more curious that the dullness to percussion which it produced was not noted until I saw him, for it had certainly been there a long time. Some thickening of the pleura is not uncommon near such cavities, and many of these were near the surface of the lung. Whatever its cause, it very effectively blanketed any direct stethoscopic evidence of cavitation, even if the cavities were large enough to give any physical signs.

I have given the clinical picture at some length because it shows how difficult it is to make sure of the right diagnosis in these cases of bronchitis due to gassing. There can be no doubt that the cardiac dilatation and albuminuria were entirely secondary to the pulmonary condition. They came on comparatively suddenly, and disappeared so very rapidly under treatment as to leave no gross post-mortem evidence of their existence.

That bronchiectasis does follow gassing has been realised for some years. It is not yet obviously common, though it will become more common every year for the next ten years. Recently I have seen a man with early generalised bronchiectasis who is, and has been, regularly at work ever since demobilisation in 1919. He was gassed and has had increasing cough all the time. He is legally debarred from applying for a pension because it is more than seven years since he left the Army. The seven years' rule of the Royal Warrant will go very hardly with these cases, and this is a point to which a wise and benevolent Minister of Pensions might well direct his personal attention.

NARCOLEPSY AS A SYMPTOM OF ENCEPHALITIS LETHARGICA.

BY C. P. SYMONDS, M.D. OXF., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN FOR NERVOUS DISEASES, GUY'S HOSPITAL; AND ASSISTANT PHYSICIAN TO THE NATIONAL HOSPITAL, QUEEN-SQUARE.

IN a very interesting paper on narcolepsy, published in a recent number of *Brain*, and discussed in a leading article in THE LANCET, Nov. 13th, p. 1017, Dr. W. J. Adie has recorded a case in which the symptoms of this disorder first appeared after an attack of encephalitis lethargica. As at the time his paper was written he was able to find only one similar instance in the literature, I have thought the following case worth relating.

I was first consulted in the case of Mr. M., aged 20, by his relations, who told me that for some time past he had been subject to attacks in which he suddenly fell to the ground. These were of brief duration and came upon him at any time. There was said to be no loss of consciousness. He was a native of Iceland and living in his own country. He had seen many medical men there and in the Scandinavian capitals, and the diagnoses of epilepsy and hysteria had both been suggested.

I saw him in April, 1925, when there was no doubt whatever about the diagnosis of encephalitis lethargica. He presented the characteristic Parkinsonian facies, and his posture and gait, though less severely affected, were typical of the same condition. With this were associated bilateral ptosis and a blinking tic. There were otherwise no physical signs of disease.

His chief complaint was of insomnia. He said that on getting up at about 9 A.M. he became so sleepy that he had to go to bed again; he was at his best in the evening, seldom getting off to sleep until well on in the early hours of the morning.

The history elicited was that at Christmas, 1918, he had an ordinary mild attack of influenza, from which he com-

pletely recovered. In the summer of 1919 he began to have a tickling feeling in the epigastrium; it began when he laughed and it was "like being tickled." Then he began to complain of excessive sleepiness. Whenever he sat down in a chair he went to sleep. There followed a period, beginning with diplopia, in which he was delirious, had hallucinations of vision, and a "funny noise" in his ears. After this he noticed that *whenever he laughed or was excited he fell down.* Subsequently he found that his face was losing expression and that saliva would dribble from the corners of his mouth; he could not read, could not concentrate, and became shaky and like an old man. In these respects he began to improve about 1922 and he was thought to be still improving, but remained liable to the falling attacks.

While giving me his history he had what I noted at the time as an attack of petit mal. My note reads: "A little twitching of the facial muscles, short interval of silence, then talked vaguely in Icelandic; then said, 'I can't move my arm.'"

Dr. Adie describes narcolepsy as comprising two kinds of attack—

"attacks of irresistible sleep without apparent cause and curious attacks on emotion in which the muscles relax suddenly so that the victim sinks to the ground conscious but unable to move."

In the case which I have recorded, both forms of attack seem to have been present at different times in the course of a prolonged encephalitis lethargica, the attacks on emotion subsequently persisting. The early story of the sensation in the epigastrium as if he were being tickled, which occurred whenever he laughed, must surely be regarded as premonitory of the complete attacks. The attack which I witnessed and which I took to be epileptic may not have been so, but raises again the relationship of narcolepsy to epilepsy in which attacks on emotion may occur. Unfortunately, considerations of time and difficulties of language prevented me from investigating the case more fully.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF SURGERY.

AT a meeting of this Section held on Dec. 1st, under the presidency of Mr. V. WARREN LOW, a discussion on the

TREATMENT OF GANGRENE OF THE EXTREMITIES

was opened by Prof. G. E. GASK. The subject of gangrene, he said, was so vast that he would limit his remarks to a consideration of the right treatment of an elderly patient with stiff arteries and threatening gangrene of the extremities. Conservative measures and amputation were admittedly unsatisfactory. He would try to assess the value of periarterial sympathectomy. Blood-vessels owed their tone to the property of unstriped muscle-fibre to be in a state of tonus and to the continuous vaso-constrictor impulses received; additional factors were the response to epinephrin and to the stretching force exerted by the contained blood. By modifying the vaso-constrictor impulses it was hoped to change the calibre of the vessels supplying the gangrenous part. Vasomotor nerve-fibrils, afferent and efferent, were present in the adventitia, and the aim in periarterial sympathectomy was to divide the efferent sympathetic fibres and so abolish control over the distal part of the vessel.

Periarterial sympathectomy in animals was followed by increased temperature or increased flow of blood to the distal portion of the limb. What happened when it was carried out on the human subject? It was first suggested by Jaboulay, of Lyons, who tried it in 1899 for perforating ulcers of the foot, and Leriche brought it into prominence for gangrene. It had also been carried out for thrombo-angeitis obliterans, Raynaud's disease, arterio-sclerotic gangrene, and even for such conditions as ununited fractures, osteomyelitis, and female pelvic disturbances. The first patient on whom Prof. Gask had performed the operation was a Russian Jew, aged 34, who gave a three years' history of pain and swelling in one leg, the blood-supply of that leg and foot being seriously impaired. While in bed both legs appeared to be normal, but when he got up and began to walk one leg became dark blue and very painful. It was generally thought that he had some obscure vascular lesion, such as erythromelalgia. For the operation a portion of the superficial femoral in Scarpa's triangle was selected, and the artery stripped of its adventitious coat for an inch. The artery at first appeared white and contracted, then the limb became warmer than its fellow; blueness and pain disappeared; the man returned to work, and was still well two years after the operation. In a second case he had partial success, while in two others no success was claimed, though the patients were no worse.

In regard to the assumption that sympathetic fibres passed to the periphery by the arteries, Prof. Gask quoted observations published in 1924 by J. N. Langley. After section of the posterior tibial nerve at the tendo Achillis, he found that stimulation of the lumbar sympathetic still caused complete pallor of the pad of the foot and the toes. Section, in addition, of the musculocutaneous nerve on the dorsum of the foot greatly reduced the pallor obtained. Additional section of the anterior nerves just above the ankle nearly abolished the effect of the sympathetic. The ganglia of the sympathetic chain sent fibres to the immediately adjoining arteries, and the peripheral arteries received small filaments at intervals from the nerves accompanying them. Langley suggested that the effect of the periarterial operation in abolishing vasoconstriction was due to some cause other than section of nerve-fibres going to the periphery in the arterial sheath, and that it might be due to section of afferent fibres.

On the whole, said Prof. Gask, the results of periarterial sympathectomy were unsatisfactory, though occasionally it met with astonishing success. In senile gangrene good results were not to be expected. There was a discrepancy between the experimental and the clinical findings, and further knowledge was required as to the distribution and function of the sympathetic fibres. If the operation had done nothing else, it had certainly broadened our knowledge of the sympathetic system. In actual or impending gangrene, should the leg be amputated, or should an attempt be made to save it by rest in bed, warmth, the application of desiccating powders, perhaps aided by sympathectomy? Though amputation might be called for in senile gangrene as a life-saving measure, it should, he thought, be staved off by every possible means.

Discussion.

Mr. W. SAMPSON HANDLEY thought Prof. Gask's desire to draw a cautious conclusion had led him to give less than its due to periarterial sympathectomy. He had himself only lost one case of senile gangrene. The operation he did, however, was not that now described, but the periarterial injection of alcohol.[1] He exposed the femoral artery in Hunter's canal, and injected, at four points in its circumference, two or three minims of absolute alcohol into the outer coat of the artery, using for the purpose a very fine hypodermic syringe. He regarded this as a great improvement on sympathectomy, chiefly because immediately after the latter a contraction of the artery ensued, and some 15 hours of low circulation preceded the onset of vasodilator symptoms, the latter lasting only three or four weeks. This period of low circulation might be very dangerous to a patient who had threatening gangrene. Moreover, injection succeeded is cases which were not amenable to sympathectomy. The alcohol injection method was the simpler operation, and its greatest field was preventive—for cases showing spots on the toes, coldness, and pallor of the feet, and pain. He agreed that

[1] THE LANCET, 1922, ii., 173.

anatomical differences in individual patients, such as variations in the level at which the vasoconstrictor nerves ran into the artery, might cause lack of uniformity in results. Langley seemed to have omitted the crucial experiment of injuring the outer coat of the artery in the dog used. Mr. Handley quoted some classical experiments carried out by Lord Lister in 1845, from which he deduced that the tone of the arteries of the lower extremities depended on the integrity of the lower half of the cord. Surgeons, he said, were at liberty to draw conclusions from their own clinical findings when these were at variance with the views of physiologists. He showed colour pictures of cases illustrating the stages in his alcohol-injection method, and giving the after-histories, which were very gratifying.

Mr. PHILIP TURNER said he had not done periarterial sympathectomy, but had treated four senile gangrene cases by the method described by Mr. Handley. The first, the most successful of his series, was that of a man aged 70, who was operated upon in February, 1924. The big toe was gangrenous, and over the whole of the foot was solid œdema, a considerable patch of apparent gangrene was at the base of the second and third toes, and another over the heads of the metatarsals in the middle of the sole of the foot. The gangrenous process had been going on three months, and there was great pain and tingling. When he exposed the femoral artery in Hunter's canal he felt very disappointed, as it was a firm, solid calcareous structure, in which no pulsation was evident. Still, he proceeded with the operation, injecting 10 minims of absolute alcohol through four punctures. After the injection a grey ring formed round the femoral artery; 24 hours afterwards the pain had gone, 48 hours later still the swelling had disappeared, and next day the patches on the sole and dorsum had practically vanished; a few days later the patient was walking about. The granulating area healed only slowly, but he did not use silver nitrate, as he feared a restarting of the gangrenous process. A year afterwards the man was walking about, the wound had healed and the pain gone, and there had been no recurrence. The next case was in a generally unsatisfactory condition when seen; diabetes, an enlarged liver, bronchitis, and emphysema were among his troubles. Following the injection of alcohol there was an improved condition, with increased temperature in the part, but only for a few days, death occurring 10 days after the operation. Death would probably have taken place whatever treatment might have been employed, or if none was carried out. He described his other cases, the result in which was moderate but not very long-lasting. He was in favour of the method, and intended to continue with it in those cases which appeared to be favourable for it. There was always the alternative of amputation if injection failed, and giving patients this chance served also to prepare their mind for the larger operation if it should be necessary. The engorgement with blood of the vessels concerned certainly was a very helpful factor. He did not think the physiological experiments Prof. Gask described could be held to negative the clinical results which could easily be observed, especially as it was evident that physiologists could not yet explain exactly what happened. He agreed with Prof. Gask that every effort should be made to stave off amputation, especially as amputation for senile gangrene showed a considerable mortality

Mr. C. H. S. FRANKAU referred to two cases of gangrene of the extremities which he had had. One was a Pole, aged 50, who had the arteries typical of that race. The speaker had operated on the patient's right leg six months previously. On his second visit he had intense pain in the left ankle and foot, which were mottled and evidently the seat of commencing gangrene. He kept the man in bed a month, trying the effect of radiant heat, diathermy, and other measures, none of which mitigated the condition appreciably. So intense was the pain that he had to be kept continually under the influence of morphia. Having read Mr. Sampson Handley's article, he, the speaker, exposed the superficial femoral artery at the apex of Scarpa's triangle, and found it to be completely blocked, pulsation being absent. Absolute alcohol was injected, and the improvement was as dramatic as in Mr. Turner's case; from that moment the pain ceasing, no morphia was given after the operation, and the man left the hospital a month later, walking with crutches on his one leg. His death took place six months later, from cerebral hæmorrhage, it having had no relation to the operation. He had two other cases, of the ordinary senile type. On one of them he did periarterial sympathectomy, on the other he carried out alcohol injection. In regard to them he could not use the term "success" nor "failure": there was no real change in the limb, and amputation was not carried out. His fourth case was a complete failure. The patient had dry diabetic gangrene, and amputation had been recommended by the physician. Sympathectomy was done instead, under local anæsthesia. The immediate result was a stoppage of the intense pain, but though efforts were made to keep the area dry, the dry gangrene became a moist one and spread rapidly, the end coming in a few days.

Mr. A. TUDOR EDWARDS spoke of two cases in which he did sympathectomy of the brachial artery for Raynaud's disease—of the finger in one case, of the foot in the other. In the first of these the operation was done nine months ago. The superficial slough separated in three weeks, eventually coming off like the finger of a glove. Three weeks later a skin graft was applied, with satisfactory result. In the other case the man had already had his left foot amputated two years before for Raynaud's disease. The artery was split in Hunter's canal, the pain disappeared immediately, and the wound granulated well, but in four months the old condition began to come back and amputation was necessary.

Mr. J. E. ADAMS drew attention to the value of ligature of the common femoral vein for the kind of condition under discussion. He had carried it out on several patients. He had found the technique of periarterial sympathectomy of the common femoral difficult, as one could not be sure of the depth to which one was going. It was necessary to be certain of getting the alcohol into the right plane. Two of the cases on which he did ligature of the common femoral vein were ordinary senile gangrene, the patients having no sugar in the urine; two had gangrene with glycosuria. In a senile case, aged 70, without sugar in the urine, in which ligation was done, pain ceased immediately, and two years later there was only slight discoloration. No swelling or œdema followed the operation. In another similar case the patient, a year after the procedure, was walking two miles in a day. In one of the diabetic cases ligation failed, and amputation had to be done in the usual way. In another case he did ligature of the common femoral vein and alcohol injection in the artery. That patient recovered from the gangrene, and the popliteal pulse, which had disappeared, returned. In a third case, ligation of the vein was not followed by any obvious improvement, and amputation was performed at the seat of election. He believed that if these cases could be seen early enough, there was a good deal of scope for surgery, short of amputation. Section of tissue removed should always follow.

Mr. E. G. SLESINGER said he had done periarterial sympathectomy 17 times (on eight patients). Two of the cases were straightforward Raynaud's disease in the upper limbs, and it was difficult for sleep to be procured on account of the intense pain. The axillary artery was chosen for the sympathectomy. He preferred this operation to that of alcohol injection. He agreed that tissue removed should always be carefully examined. Twice he had done the operation in frank thrombo-arteritis obliterans. It was possible that the condition being dealt with was capillary dilatation, not arterial dilatation. He would not do

it again in thrombo-arteritis obliterans, but in the other cases he had been favourably impressed with the operation.

Mr. C. MAX PAGE said the operation of sympathectomy certainly relieved the subjective symptoms. He agreed with Mr. Slesinger as to the extraordinary variety in the appearance of the artery in different people when it was exposed. It was likely that the operation would be done increasingly in the near future, therefore it was of great importance that as much knowledge as possible should be obtained as to the arterial disease and the circulatory conditions present, examinations being made of middle-sized arteries in the immediate neighbourhood, with blood-pressure readings.

Mr. J. PATERSON ROSS said the suggestion had been made that the nerve-fibres stripped from the vessel in the so-called periarterial sympathectomy might be of afferent nature, not efferent. He showed a coloured diagram to explain the point. The muscle in arteries was believed to be in a state of tonus, and it was similar to that in striped muscle. The tone of striped muscle depended somewhat on the reflex arc, the afferent fibre of which started in the muscle, passed in by the posterior nerve root, and formed a synapsis in the cord, thence passing back to the muscle itself. There was evidence that that was the afferent track, because section of posterior nerve roots lowered the muscle tone, and that had been used for many years in the treatment of spastic states. Some afferent fibres passed from the blood-vessels to the cord, some perhaps carrying sensation, others serving the protopathic sense. When, therefore, an afferent nerve was cut, so interrupting the reflex arc, it was possible for the tonal effect of the vasoconstrictor nerves to be interfered with. Probably it was in the periphery that the vaso-constrictor fibres exerted their chief effect, and the varying character of the results obtained in senile gangrene might be attributable to the pathological changes in the different parts of the vessels.

Dr. PARKES WEBER said the symptoms indicating that gangrene threatened were: first, intermittent claudication in elderly people—a feeling of cramp and tiredness after walking a short distance; secondly, failure to detect pulsation in the dorsalis pedis artery, with coldness and a purplish discoloration of the tissues, especially when in the dependent posture; and, lastly, the formation of slight patches of discoloration and ischæmic ulcers. These early symptoms, properly treated by rest in bed and iodide of potassium, with a restriction of exercise afterwards, did not, in many cases, develop further, and surgery did not have to be considered.

Reply.

Prof. GASK said he did not take sides concerning the operation of sympathectomy. The discussion seemed to bring out clearly that clinicians had found, in a number of cases, definite advantage following the procedure; there was increased warmth in the limb and relief of pain. Mr. Ross's suggestion should lead to a fruitful line of work. The discussion also seemed to make it clear that sympathectomy was worth proceeding with. He did not lose sight of the fact that improvement usually followed up to a certain point from the mere taking of the patient off his legs and keeping him in bed.

LONDON POST-GRADUATE HOSTEL.

CEREBRAL LOCALISATION IN THE CLINICAL SUBJECT.

AT a meeting held at the Post-Graduate Hostel, Imperial Hotel, Russell-square, W.C., on Nov. 25th, Dr. GORDON HOLMES presiding, Dr. W. J. ADIE opened a symposium on this subject with an account of the localising signs in disease of the prefrontal lobes. He pointed out that the diagnosis was always uncertain, as most of the signs that are considered to be characteristic of disease of the frontal lobes were negative, none were constant, all might be absent in a given case, and all might be indirect results of a distant lesion. Mental changes were fairly constant and were important; they might appear in the loss of power to concentrate, loss of initiative, persistent punning and elementary joking. Dr. Adie related a number of illustrative cases, including some in which diagnosis had been made on the mental symptoms alone. He then described in detail two less familiar signs of frontal disease—namely, exaggeration of Mayer's reflex (proximal phalangeal reflex) and the peculiar grasp reflex which is sometimes found in the hand on the side opposite to the tumour. Every case he had seen in which a unilateral exaggeration of Mayer's reflex had been present had had a unilateral tumour on the opposite side. Any light touch on the palm caused the involuntary grasping movements of mixed flexion and extension; when the object was grasped the patient was unable to let go, and tightened his hold at any attempt to remove it. After it had been removed, the patient would open and close his fingers gropingly. There were other signs, and the speaker was hopeful that more would be found and that the "silent" areas would become fewer.

Jacksonian Epilepsy.

Dr. E. A. CARMICHAEL said that in true Jacksonian epilepsy the patient had a definite sensory aura. In a second type, the progressive convulsion, the patient remembered nothing, but the relatives noticed that the attack started on one side and spread thence; they alone could give any indication of the side of the brain that was affected. In a third type twitchings began, during full consciousness, in one limb, toes or fingers, and spread to the elbow, shoulder, &c. The patient could relate the exact sequence of the attack, but had no sensory aura at all, no gastric sensation, no numbness, and no ocular phenomena. Lesions in the parietal region were associated with numbness or some curious sensation; the sequence of the sensory phenomena did not always fit in with the anatomical relations of the post-central gyrus. In occipital lesions the patient complained of "lights in front of the eyes." Inquiry showed that these lights were on one side and were usually coloured red, green, and blue. These might be the only signs of an occipital tumour. Lesions in the uncinate gyrus were associated with a champing movement and a smacking of the lips, and a peculiar taste or smell which no one else present could appreciate. These fleeting sensations passed on into a dream state in which the patient was almost somnambulistic Disturbances in the posterior part of the temporal lobe often produced no physical signs. The speaker quoted one case whose only trouble was hallucination of people seen over his left shoulder and always passing away to the left as he turned to focus them. The tumour was on the right side. Lesions in the subtentorial region had been described by Hughlings Jackson and Dr. Gordon Holmes as causing tonic convulsions. The speaker, however, had seen 82 cases of gunshot wounds of the cerebellar region during the war, and had never seen anything that could be described as or compared with an epileptiform seizure. He thought the convulsive symptoms in these cases were due to hæmorrhage into the ventricles—certainly not to cerebellar disease. Localisation was considerably aided by a definite history of the nature of the attack and the phenomena that preceded it, the general convulsion, and the observations of the relatives. It must not be thought that all cases of Jacksonian epilepsy had cerebral tumours; in 71 gliomata investigated by him there were only 18 cases of epilepsy, and in 13 epitheliomata of the brain only seven cases showed epilepsy. Jacksonian epilepsy suggested an endothelioma rather than a glioma.

Help Given by the Visual Fields.

Dr. MACDONALD CRITCHLEY said that the optic pathway, on account of its length, was very apt to be affected by lesions within the hemispheres, and

that no clinical investigation was complete without a perimetric chart of the visual fields. Progressive restriction from without inwards was liable to occur in consecutive atrophy following long-standing papillœdema, and must in these cases be discounted as a localising sign. Tumours in the front of the under surface of the optic lobes might press on the optic nerve between the orbit and chiasma, producing rapid blindness in one eye only, with loss of central vision, especially for colours. Retinoscopy showed a characteristic picture of a pale sharply-cut disc on the blind side and vascular engorgement on the other. Lesions about the chiasma were mostly produced by the pituitary; pituitary tumours usually pressed on the chiasma from below and behind, those of the infundibulum from above and behind. A clear-cut bitemporal hemianopia was rather uncommon. If the tumour pressed on one tract only a homonymous hemianopia would result, with early involvement of macular vision, which was a physiological feature of tumours of this region. The result was an enlargement of the blind spot and a central or paracentral scotoma. This would be soon followed by peripheral defect on the temporal side, until the two fused to form an upper-sector defect, and later a complete hemianopia. The nasal field suffered last, being gradually restricted in a bean-shaped manner. Lesions between the chiasma and the cell stations produced a homonymous hemianopia, very different from that produced by lesions behind the cell stations, in which the macular fibres tended to escape. Lesions of the optic radiations in the temporal, parietal, and occipital lobes tended to produce a homonymous hemianopia, but as in the temporal lobe the visual fibres were splayed out, only a portion of them were usually involved by tumours in this lobe, and so the result would be a quadrantic hemianopia. In the parietal and occipital lobes the fibres were packed more closely and lay nearer the surface, and so were more likely all to be caught by a tumour. The points of distinction between lesions behind and in front of the geniculate body were that in the posterior tumours central vision tended to escape, the patient was often unconscious of his field defects, Wernicke's hemianopic pupillary reaction could be obtained, and "optic nystagmus" varied. In certain cases of superficial temporal tumour which touched without damaging the visual fibres, the patient would be unable to appreciate an object at the periphery on the side opposite to the lesion if it were presented simultaneously with another object on the other periphery.

Radiographic Localisation.

Mr. A. P. BERTWISTLE described a method of localisation of cerebral tumours by X ray, with a key radiogram and a "gyrometer." The key radiogram was prepared by photographing the half of a sagitally-divided brain and skull with a mixture of red lead and warm vaseline painted along the chief sulci. Over the head was fitted a scale made of 7 in. of watchspring with the ends connected by a piece of elastic; at 1 in. intervals seven strips of 4 in. spring were fastened at right angles to the central one. Silver wires were threaded through holes 1 in. apart in the verticals. The preparation was carefully orientated and radiographed, and the key thus provided formed a valuable localising guide for the central area. The gyrometer was a thin strip of celluloid tape provided with a cursor at right angles, and this served to localise the brain underlying a cranial defect in the living head. The speaker described a case of depressed fracture over the angular gyrus in which the site of injury was located radiographically.

Dr. G. E. GERKEN described a case of aphasia which had been under his care in Boston. The man was admitted about midnight with a parietal hæmatoma. Next day X rays revealed a crack of the inner table over the Rolandic fissure. Three days later he showed signs of consciousness. On the fourth day he began sentences, but was unable to finish them; on the fifth day he had a similar motor aphasia. As there was no increase in symptoms he was not operated on. Two years later he was seen in a State institution; he had got back the use of his arm after several months, but still had some aphasia.

The CHAIRMAN said that it was not possible to judge Dr. Gerken's case at this interval of time, but in general, if there were no progressive symptoms, it was better to leave well alone; any man was better with a whole skull than with a hole in his skull. He described a case seen by him recently—a woman who had had a series of epileptiform seizures of increasing frequency. Before the first she had had a momentary glimpse of two women in blue and white, with caps and aprons. One of them had a curious leer on her face, and the other appeared threatening. She had a feeling that this one was pulling her head round and dragging her eyes out of their sockets. In subsequent attacks she had rarely seen the figures, the seizures occurring more often at night, but the patient was still very conscious of this sensation of being pulled round. Treatment by suggestion had failed. Lately she had also had a curious smell and taste, and numbness in her right hand. There was definite evidence of a cerebral lesion, probably a cyst in the temporal lobe. Complex visual sensations were always due to lesions of the inner aspect of the temporal lobe. Where the visual cortex itself was the source of excitation, the patient saw simple flashes of light, with or without colour. Dr. Adie had put forward some definite positive signs of frontal lesions, but these were not found in every case, and so far no absolute rules could be made.

MEDICO-LEGAL SOCIETY.

CARBON MONOXIDE POISONING.

A MEETING of this Society took place on Dec. 2nd at the rooms of the Medical Society of London when, in the absence of the President, the chair was occupied by Mr. WALTER C. WILLIAMS, and Dr. DOUGLAS KERR (Edinburgh) introduced a discussion on the medico-legal importance of carbon monoxide poisoning.

One of the greatest social problems of the present day, he said, was the increase in the number of suicides. Every decennium showed an increase in the suicide rate in this and other countries. The chance of dying by suicide was more considerable than anyone not studying the statistics would imagine. One out of every 119 young men reaching the age of 20 ultimately died by his own hand; and last year, of all the males over 20 years dying in England and Wales, 1 in each 65 was a suicide. An interesting study was that of the changing methods in vogue among suicides. In former years the most frequent means of voluntarily ending life were hanging, drowning, cut-throats. These methods still prevailed, but no longer held the prime place, which was taken by poisons; and of the poison methods the most frequent was coal-gas (carbon monoxide). In Scotland not only was that the most frequent poison used, it was the most common of all methods of suicide. In 1899 Prof. Harvey Littlejohn investigated the suicide statistics of Edinburgh for the 30 years ending 1895, and found that the total of 298 did not include one of coal-gas poisoning. But for the years 1920-25 there were 353 suicides, of which 105, or 30 per cent., were due to the inhalation of coal-gas. In some other Scottish towns the percentage was even higher. The method was used by 42 per cent. of the women, as against 25 per cent. of the men. In England the number of suicides by this means had more than trebled in the last six years, while the number of deaths accidentally caused by coal-gas inhalation showed little variation.

The large increase in coal-gas suicides gave rise to several important medico-legal questions. Bakers' ovens and other fixtures in manufacturing establishments figured in the suicide cases as well as the domestic gas oven. Among the cases of death by accident were those in which there was a defective

gas main from which the gas percolated through the soil and poisoned the persons in the vicinity, as in the recent case at Peterborough. In Edinburgh, during the last six years, there had been only seven unquestionable cases of death by gas owing to accident. In many of the suicide cases the victims were found with their heads covered with coats or blankets, to ensure that the gas did its work thoroughly, the gas-tube being secured under these coverings. In some the gas-tube was found still clasped in the hand. In the case of one woman, she wore a mask which had been made out of the tea-cosy. But it must always be remembered that this staging might well be arranged around his victim by a murderer, the time chosen being when he or she was asleep. An interesting case which Prof. Littlejohn investigated was that of a labourer who was employed down a well. A post-mortem examination was ordered on account of the lividity noted after death. It had been said that on returning from work his clothes smelt strongly of gas. But the man left his work at midday on the Saturday, went to his home to dinner, and afterwards walked about the town, returning home about midnight, sleeping afterwards in the kitchen, where burned a coal fire. In the morning he was dead. When coal-gas had been inhaled in concentrated form, five or six hours' breathing of fresh air sufficed practically to clear the air from the system. In this man, though he had been walking about most of the afternoon and evening, the saturation was 70 per cent., therefore any gas from the well must be left out of account. He was gassed in the dwelling-house, but whether it was homicide or suicide could not be determined.

Four chief questions arose in connexion with this subject: (1) the possibility of a mistaken diagnosis; (2) the degree of toxicity and the amount of saturation needed to cause unconsciousness; (3) the time elapsing before a person became unconscious; (4) the rate of elimination. As to mistakes in diagnosis, rarely the appearance—very similar to that left by coal-gas—might be due to the post-mortem formation of nitroxy-hæmoglobin, as in a case reported by Haldane last year. Carbon monoxide gas united with the blood much more readily than did the oxygen of the air, and it caused death not by toxic action so much as by depriving the tissues of the oxygen which it displaced. When the saturation reached 50 per cent. there were distinct symptoms of malaise and weakness; when the 55 per cent. point was reached there was difficulty in walking, and beyond this unconsciousness supervened. With a rapid entry of gas the symptoms came on with a less degree of saturation. Immersion in a gas oven with the gas containing 22 per cent. of CO, as in Edinburgh, would result in unconsciousness, theoretically, in 30 seconds. Elimination of the gas during the first one and a half hours was slow, but after that the rate was accelerated.

Could measures be undertaken to limit recourse to gas for suicide purposes? Most of the CO was obtained from the water-gas which was added to coal-gas to increase its heating properties. The rate of accidental poisoning by gas was two and a half times higher in cities where water-gas was employed than in others. Any alteration in the composition of the gas supplied for domestic purposes did not seem to be a practical proposition. Parliament had inquired into the question of accidental deaths due to gas poisoning, but left the question of suicide alone. Yet there was no important increase in the number of accidental deaths from this cause. Fatal results had occurred when the penny-in-the-slot method of supply was used, and a woman suicide in Leeds borrowed the penny from a neighbour to get the 25 cubic feet of gas which ended her life.

Dr. KERR was of opinion that the great amount of publicity given to cases of suicide by this means had a bad effect on the ill-balanced section of the community, as they were so susceptible to suggestion. When an unusual means was reported in the daily press it was the experience that another instance by the same method soon followed. Ease and apparent freedom from discomfort also played a part in a miserable person deciding to terminate his life. A particular bridge with a low parapet had been for a long time a favourite venue for suicides, but when the authorities made a high parapet, edged with spiked railings, there were no more attempts there.

Discussion.

Sir WILLIAM WILLCOX agreed with Dr. Kerr as to the undesirability of broadcasting minute particulars of suicides, whatever the means taken, as imitation was a large incentive to crime. This was seen not very long ago when weed-killer was used by several people to get rid of those they wished removed. CO was, perhaps, the most insidious poison known. He was sorry Dr. Kerr did not enter into the symptomatology and treatment of the condition, and he asked whether any special treatment was pursued in Edinburgh in addition to the usual oxygen, fresh air, and stimulant treatment. Was injection of oxygen into the tissues or the intravenous use of a suitable solution of peroxide of hydrogen carried out? He had used the latter himself in some cases of the kind with apparent success. A further cause for disquietude was the increasing percentage of CO used in the coal-gas supplied. He spoke of a curious case which was in his wards recently, that of a woman who was admitted because of alleged coal-gas poisoning, and her colour was consistent with that idea. She had penny-in-the-slot gas, and finding that her room was a rather large one, he did not think the required saturation could have been produced. In the room was an empty chlorodyne bottle. Her blood showed only a 20 per cent. saturation with CO, and this would not produce unconsciousness. Dr. Webster found morphine in the urine, and the blood-urea was very high. The fatal issue was really primarily due to very inadequate kidneys, but she had taken two accelerators. This case conveyed a warning against hastily arriving at a conclusion; there should be a careful examination of all the circumstances. Sometimes natural disease simulated the symptoms of coal-gas poisoning.

Dr. ROCHE LYNCH suggested that the alarming increase in suicides by means of coal-gas might not appear quite so great if allowance was made for the increase of the population in the period under review. The rate per mille seemed the best way of arriving at a comparative estimate. He thought the provisions of the Dangerous Drugs Act had played a part in determining coal-gas as such a frequent means of taking life, as drugs formerly used for the purpose were now difficult to procure by ordinary people. Also, the increased average length of life might lead people of advanced years, the subjects of such diseases as cancer, to put an end to their sufferings. With regard to treatment in America the oxygen administered was mixed with 5 per cent. carbon dioxide in order to counteract the tendency to alkalosis which these people showed.

Dr. MORGAN FINUCANE, looking at the question from the standpoint of the public, said that if people determined on committing suicide they would do it by some means or other. He had been medical officer to the Gas Light and Coke Company, and it was his duty to attend inquests on cases of death from this agent. Could nothing be done by scientists to mitigate its lethal properties? He agreed that the increase in the figures shown was alarming, and that the gas was a very dangerous one. He urged more stringent regulations in regard to gas fittings, that no house should be inhabited until a most rigorous examination had been officially made of all pipes, and that there should be a periodic inspection of all gas mains. Electricity afforded a natural relief from the anxieties following in the wake of gas usage.

Mrs. BLANCO WHITE said she had been assured, by an official of the Ministry of Health, that a group of suicides by gas during recent years were men who had been badly wounded in the war and whose subsequent existence and suffering led to this fatal ending. That was confirmed by the Ministry of

Pensions. On the practical side, she suggested that chemists should try to incorporate in coal-gas something which would cause fits of sneezing in those inhaling it.

Dr. DANFORD THOMAS agreed that in these matters imitation had a bad effect, and that there was too much publication of details in these suicide cases. He had interviewed persons who recovered from gas poisoning, and they declared the effect was that of a pleasant dream. He advocated the placing of gas ovens and other receptacles at a greater height from the floor than was customary, then people would not feel they could so easily lie down to secure their passage from life.

Dr. W. D. NEWCOMB referred to statements in text-books that in cases of poisoning by coal-gas areas of softening were found in the brain and hæmorrhages in the basal nuclei. He had not seen these lesions in such cases.

Dr. BERNARD O'CONNOR said he would have thought transfusion of blood would have been the appropriate treatment for coal-gas poisoning, seeing the insidious way in which the poison affected the blood. He believed it was successfully employed some years ago.

Reply.

Dr. KERR said the mixing of 5 per cent. CO_2 with the oxygen used stimulated the respiratory centre, and elimination of the gas proceeded quicker. This method was held to have successfully replaced treatment by blood transfusion. The figures of increase would have appeared little less formidable if account had been taken of the increase of population, for the latter was relatively small over the period. In England and Wales in 1913 there were 276 cases of gas suicide, 149 accidental gas deaths; in 1923, 688 and 178 respectively, and in 1925, 762 and 163. In Scotland in 1913 there were 10 suicides from coal-gas, and 267 by other means; in 1923, 70; in 1924, 91; while the deaths by other means were 257 in 1923, 284 in 1925. Most suicides were committed between 45 and 55 years of age, and the number was very small after the sixty-fifth year. Accidental cases had increased by only 20 in six years. He had seen lesions in the brain after coal-gas poisoning of a character easily demonstrable to students. He agreed that electricity was the remedy for the evils which had been disclosed.

ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION.

A QUARTERLY meeting of this Association took place on Nov. 16th at the Horton Mental Hospital, and later at the West Park Mental Hospital, Epsom. Lieut.-Colonel J. R. LORD, the President, took the chair, and Dr. P. K. MCCOWAN read a paper written by himself and Dr. J. S. HARRIS on

Chronic Epidemic Encephalitis.

Hyoscine, they said, could be regarded as a specific in the treatment of encephalitic Parkinsonism. They had investigated carbohydrate metabolism as represented by the blood-sugar curve, and had made experiments on muscular tonus and on altered affectivity, as shown by the psychogalvanic reflex, and they had found that abnormality in these functions in patients with encephalitis could be partially corrected by hyoscine. In the normal person subcutaneous injection of 1/100th of a grain of hyoscine hydrobromide was followed, in 10 to 15 minutes, by dryness of the mouth and throat, a sensation of giddiness, some mental confusion, slurring of speech, and inability to walk straight. There was also marked impairment of accommodation, so that none but the largest print could be read. Later there followed a feeling of laziness or fatigue, and if left to himself the person would fall asleep and remain asleep for several hours. Thus it was evident than in normal people the effects of hyoscine were depressant—a result contrary to that seen in encephalitis. It practically all cases of this disease a suitable dose of hyoscine caused improvement; the general muscular rigidity was reduced, while tremors of the face and extremities and excessive salivation and lacrymation disappeared. The patient's alertness was also increased, articulation was improved, and some expressiveness crept into the rigid countenance.

The functional aura, went on Dr. McCowan, was found in encephalitics more definitely than in any other group of patients gathered in a mental hospital, and this, they thought, gave a clue to the discovery of an organic basis for the so-called functional nervous disorders and psychoneuroses. In encephalitis lethargica there might be subtle biochemical or biophysical abnormalities. The lesion involved the basal ganglia, a centre of prime importance in the instinctive and emotional life of man. Dr. McCowan further described laboratory investigations carried out in conjunction with Capt. S. A. Mann at the Maudsley Hospital. [Some of these they have already reported in THE LANCET, 1926, i., 802.] The effect of injecting 1/100 gr. of hyoscine was to cause hypoglycæmia, but there might be a secondary hyperglycæmia two hours after the glucose meal and the drug injection. Similar results were obtained with atropine. These drugs also caused inhibition of the external secretion of the pancreas and a general arrest of the secretions of the alimentary tract. The blood-sugar values obtained in encephalitis were consistent with the theory that it was a chronic toxæmia. The results of the injection of hyoscine simultaneously with the ingestion of glucose permitted of a classification of the cases into two groups: (1) those exhibiting Parkinsonism with a depression of blood-sugar; (2) those, not exhibiting Parkinsonism, in which the blood-sugar curve did not show improvement after the injection. Hyoscine could be given either subcutaneously or by the mouth, but the best effects followed a combination of the two methods; 1/100 gr. was injected in the morning, and 1/50th gr. was given by mouth during the day. Some of the unpleasant effects were combated by giving 1/10 gr. of pilocarpine. Some patients had been having hyoscine for two years, and no deleterious effects were traceable. The action of the drug was only temporary, and when it was discontinued there was a relapse into the former state. Stress was laid on the fact that these patients were still suffering from an active disease, not the mere after-effects of an acute process. The treatment must still be regarded as in the experimental stage. In a trial of various drugs in the treatment of chronic encephalitis two had been found very helpful—namely, tryparsamide and argotropin. These were given to all cases of both types. Tryparsamide seemed to gain access to the central nervous system in a way that no other arsenical preparation appeared to do, and no case had shown progress of the disease since it was given. The course was eight weekly injections of 2 to 3 g.

Dr. HARRIS demonstrated cases, and Major N. ROBERTS welcomed the guests to the hospital.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

EXHIBITION OF CASES AND SPECIMENS.

A MEETING of this Society was held in Sheffield on Nov. 19th, Mr. W. GOUGH (Leeds), the President, in the chair.

Miss FRANCES IVENS (Liverpool) showed a specimen of

Melanotic Sarcoma of the Clitoris.

The patient was aged about 58, 8-para, and very stout. She had noticed a small lump in the anterior portion of the vulva for a year.

The clitoris was replaced by a softish nodular growth, pigmented in patches, which extended on to the left labium minus and the prepuce of the clitoris was stretched over the tumour. The growth was movable on the deeper structures. In April, 1925, Miss Ivens excised the whole vulva as radically and deeply as possible. No enlargement of the inguinal glands could be detected and so far there had been no recurrence

The tumour consists of masses of spindle cells with well-stained nuclei arranged in an alveolar manner in a connective tissue stroma. Granules of brownish pigment are scattered through the connective tissue and are present in some of the cells, but in some areas pigment is absent. The tumour is covered by thinned-out stratified epithelium.

Cases of melanotic sarcoma of the clitoris, said Miss Ivens, were very rare, and said to be extremely malignant. It was possible that this tumour arose from the chromatophores or connective tissue pigment cells of the skin, and was therefore a melanotic sarcoma and not a sarcoma associated with altered blood pigment—or sarcoma hæmorrhagica. Miss Ivens also showed a specimen of

Endometrioma of the Broad Ligament.

The patient, aged 20, had suffered from severe dysmenorrhœa with profuse and prolonged menstruation from the onset when aged 15. Bilious attacks had been frequent, and two years ago there was severe abdominal pain with vomiting. The cervix was dilated in January, 1925, but the condition grew worse, and in December, 1925, Miss Ivens opened the abdomen, removed a swollen, kinked, and unhealthy-looking appendix, and incised some small cysts of the ovaries. In the right broad ligament close to but not adherent to the body of the uterus was a swelling the size of a large marble, dark in colour. There were no adhesions. It was enucleated and the peritoneum stitched. The tumour proved to be a cyst containing dark tarry fluid, was lined by cubical epithelium, and showed in its wall typical endometrial stroma and glands embedded in and surrounded by fibrous tissue.

This case, said Miss Ivens, was interesting as it supported the view that endometriomata were due to fœtal displacement of Müllerian tissue and not to endometrial grafts. A somewhat similar specimen, belonging to Dr. Everard Williams, had been shown at the Royal Society of Medicine last year.[1]

Ovarian Tumours and Uterine Tumours.

Dr. J. W. BRIDE (Manchester) showed specimens of ovarian tumours.

CASE 1.—He saw the patient, a girl of 15, on Sept. 29th last on account of persistent vomiting and acute left-sided abdominal pain. Her pulse-rate was 130 and temperature 101° F.; there was great rigidity in the hypogastrium and inability to pass water. The symptoms dated from a menstrual period about a week before, and there had been regular menstrual periods since the onset of menstruation in August, 1925, always with dysmenorrhœa. An indefinite mass was to be felt in the left iliac region. Ovarian cyst with twisted pedicle was diagnosed and at operation a dermoid cyst, black in colour and about the size of a fœtal head, was found lying in the utero-vesical pouch. The right tube and ovary were normal. The cyst was removed and the patient made a good recovery.

CASE 2.—Fibromata of both ovaries were found in a virgin of 19 years complaining of pain and swelling in the hypogastrium with primary amenorrhœa. For her age the patient was distinctly childish and she had had no molimina. A hard mass, non-mobile and tender, was felt in the left iliac region, and per vaginam the pelvis was found to be filled with hard nodular growths. At operation Dr. Bride found the large left and smaller right ovarian tumour, and, being doubtful of their nature and feeling sure that all ovarian tissue was destroyed he performed panhysterectomy. There was no ascites. The patient made a good recovery.

Dr. Bride said that Hoon, writing in *Surgery, Gynecology, and Obstetrics* in 1923, had stated that fibromata of the ovaries might occur at any age after puberty, that there might be comparatively few symptoms, that ascites did not necessarily mean malignancy, and that menstruation was usually normal. In text-books it was often said that ascites was found so often with fibromata as to be almost a symptom. Ought not this statement to be modified? In the cases he had seen ascites had never been present. Pain, he thought, was in this case an important symptom in making the diagnosis against fibroids.

MR. J. ST. G. WILSON (Liverpool) described an unusual case of carcinoma of the cervix.

A nullipara, aged 30, married seven years, complained of intermenstrual bleeding for four months. The cervix was replaced by a crater, ulcerating, friable, and bleeding; the supravaginal cervix was thickened and the uterus fixed. There was albumin in the urine. At operation growth was seen on the surface of the uterus. The patient died ten days afterwards; the specimen showed infiltration of the whole uterus; the tumour was a squamous-celled carcinoma, and secondary growths were found in the lumbar glands.

Dr. E. O. CROFT (Leeds) commented on the rarity of spreading to the corpus.—Dr. K. V. BAILEY (Manchester) asked if sections of the upper portion of the growth had been cut to exclude its being a different growth from the cervix.

Prof. W. F. SHAW (Manchester) showed a case of acute torsion of a uterus containing a fibromyoma.

The patient, aged 70, had complained for 18 months of recurrent attacks of nausea which had been put down to biliousness, but on the last occasion her doctor had examined the abdomen and found a large, hard, tender tumour which, she stated, had been there for over 25 years. The tumour was very hard, extended to the umbilicus, was apparently fixed to the uterus, and was extremely tender.

At operation it was found that the fundus uteri contained a fibroid the size of a fœtal head and of stony hardness due to calcareous degeneration. The uterus and appendages were twisted round in two complete turns, and so had formed a narrow pedicle just above the level of the internal os no thicker than a man's finger. The broad ligaments and tubes were of a deep purple colour, many of the veins were thrombosed, but in some the blood was still fluid, so apparently there was a small circulation still kept up. The tumour was easily removed at the site of the torsion and the patient made an uninterrupted recovery.

Prof. M. H. PHILLIPS (Sheffield) described a case of

Advanced Abdominal Pregnancy.

His object, he said, was to draw attention to the difficulty of clinching the diagnosis of an advanced abdominal pregnancy by the ordinary means of examination. In the present case, although palpation failed to define any part of a fœtus in the abdominal tumour, an X ray photograph by Dr. J. L. Grout had shown not only a fœtus, but also a position and condition of that fœtus which could best be explained by its being dead and in an extra-uterine sac.

Two and a half years ago the first pregnancy of the patient, whose age was 30, ended in miscarriage at 11 weeks and a dangerous attack of pelvic peritonitis. Menstruation was scanty afterwards, but she did not miss a period until March, 1926. Her last period was on Feb. 13th. There was a slight show unaccompanied by pain nine weeks after. Morning vomiting, secretion in the breasts, steady enlargement of the abdomen duly followed. She quickened at four and a half months and felt movements daily until Sept. 4th. On that day she had severe abdominal pain accompanied by a dark bloody discharge and also diarrhœa and vomiting. Premature labour was suspected and her doctor took her into a maternity home. The external os just admitted the finger-tip but not more, and in the course of six days the pain and vomiting ceased and the patient was sent home.

No further fœtal movements were felt, however, and the breasts and the abdomen lessened in size. A slight, very dark, bloody discharge occurred daily. When seen by Prof. Phillips on Oct. 21st (36 weeks after the last period) she had a globular elastic mass visibly distending the abdomen and reaching from the pelvic brim to a point 2 inches above the navel. It possessed none of the signs of an enlarged uterus and no fœtal parts could be made out. On vaginal examination the cervix was soft, the os was closed to the finger, and bimanually the slightly enlarged body of the uterus could be felt behind and to the right of the lower pole of the abdominal tumour, which could just be reached at the pelvic brim. The pelvo-abdominal tumour felt just like an ordinary cystadenoma of the ovary.

The abdomen was opened on Nov. 12th, and on incising the peritoneum a pint or so of thin clear fluid escaped from a localised space, within which was exposed a second sac—the amnion—closely shrouding the fœtus. This sac contained rather less than half a pint of thick, greenish, opaque fluid. Both fluids were odourless. The fœtus was lifted out and the cord divided. The sac was now seen to line the true pelvis and the abdominal cavity to above the umbilicus. The transverse colon, adherent to the abdominal wall, formed the upper limit of the gestation sac. The placenta was found plastered on the upper half of the sacrum and the adjacent lower half of the lumbar spine. It was of a dull grey colour and appeared bloodless. No attempt was made to separate it from the underlying aorta and other large vessels. The patient was now going on well.

Dr. CROFT demonstrated a specimen showing axial rotation of a fimbrial cyst.

Mr. W. W. KING (Sheffield) read a paper on Some Aspects of Concealed Accidental Hæmorrhage, discussion on which had to be postponed.

[1] THE LANCET, 1925, ii., 1228.

Reviews and Notices of Books.

INCAPACITY OR DISABLEMENT IN ITS MEDICAL ASPECTS.

By E. M. BROCKBANK, M.B.E., M.D., F.R.C.P., Hon. Physician, Royal Infirmary, Manchester. London: H. K. Lewis and Co., Ltd. 1926. Pp. 120. 7*s.* 6*d.*

THE certification of incapacity or disablement, whether as the result of disease, injury, or accident, is a responsible duty which devolves upon most medical men in active practice, more especially upon those concerned in National Health Insurance practice. The widespread effects of the Workmen's Compensation and Employers' Liability Acts also impose upon medical practitioners important duties in this regard. The growing tendency to the development of pensions schemes for workers will naturally increase these duties and bring about special problems in assessment of incapacity and its certification. The fact that disputes upon such questions are inevitable, and that they often have to be settled by arbitration and sometimes by litigation, has resulted in a specific legal interpretation of certain terms in more or less common use. It is necessary for those giving certificates in connexion with disability or incapacity claims to have some knowledge of these special meanings, and some acquaintance with the law affecting certification in these matters. Dr. Brockbank, of Manchester, who has had a wide experience of insurance problems, has published a book which we can cordially recommend. The information it contains was collected for his own guidance, but will prove of the utmost value to others engaged in practice. He begins by defining incapacity or disablement, and points out that the law distinguishes between "incapacity to work" and "incapacity for work"—the former denoting total disablement for all work, while the latter means only some disability which restricts working capacity. The effects of accident and disease upon the working capacity are considered from the points of view of the worker and of the employer. The medical and surgical causes of disablement are next considered, and the alphabetical arrangement adopted facilitates reference. The influence of each upon the working capacity is described in an interesting way, and illustrative cases are quoted. In conditions where disease such as aneurysm, heart affection, or epilepsy has been a factor in death during employment, the circumstances in which claims have been successful or unsuccessful are described, and authorities are quoted.

Dr. Brockbank's book is timely in its publication, and it should serve a useful purpose.

RENAL SURGERY.

By F. McG. LOUGHNANE, F.R.C.S., Surgeon to St. Mary's Hospital, Plaistow; Assistant Surgeon, All Saints' Hospital for Genito-Urinary Diseases. London: Longmans, Green and Co., Ltd. 1926. Pp. 210. 10*s.* 6*d.*

THE avowed object of the author is to convey to the student and general practitioner an up-to-date knowledge of the surgery of the kidney in as concise a manner as possible. There are four preliminary chapters which describe the anatomy of the kidney, the changes in the urine in renal disease, the estimation of renal function and pain in kidney disease. The following chapters are devoted to the several diseases which attack the kidney, ending with one on operations.

In the interests of conciseness, we may suppose, dogmatic statements are made, some of which are by no means generally accepted. For example, the author says that in renal tuberculosis ureteric catheters should always be passed on each side. No mention is made of any possible danger associated with this procedure, the ill-results of which, as Wildbolz points out, may not be manifest for many months. Again, in bilateral stone it is recommended to remove that from the more damaged kidney and to wait three to four months before taking the stone out of the healthier one. Many surgeons prefer to reverse the procedure and at any rate save the less affected organ. We are told that nephrectomy for hydronephrosis should never be performed unless "absolutely essential," as in most cases functioning renal tissue is present. This is true, but we are not informed how uncertain are the results of plastic operations upon the ureter and pelvis, nor when nephrectomy is regarded as absolutely essential. Mr. Loughnane says that the renal pelvis should never be injected under anæsthesia, because damage may be done. But if a proper apparatus be used, injury by injection is impossible, and the real objection to anæsthesia is that the patient cannot hold his breath to have the pyelogram made. This applies equally to children in whom the author, a few pages on, says the injection may be made under general anæsthesia. On page 77 the statement is made that hydronephrosis can be cured by renal sympathectomy. The evidence, however, on the value of this fascinating operation is, up to the present, anything but conclusive. Possibly ureteric stone is not considered to come under the term renal surgery, for there is no systematic account of this condition and how to deal with it. Among functional tests, the author places most reliance upon the indigo-carmine and the urea-concentration test. He does not believe that a blood-urea estimation is so good an index of suitability for prostatectomy. We are glad to see that the long sojourn of a catheter in the ureter is deprecated in more than one place.

The book is nicely produced, with some good pyelograms; the illustrations of specimens would have been clearer if reproduced from drawings rather than from photographs.

THE X RAY IN EMBRYOLOGY AND OBSTETRICS.

By W. A. NEWMAN DORLAND and M. J. HUBENY. London: Henry Kimpton. 1926. Pp. 420. 50*s.*

EMBRYOLOGY has been the subject of radiological research from its earliest days. This volume is rather an epitome of the extensive literature on the subject than an original contribution—in fact, it is difficult to find evidence of any original work, even the illustrations being attributed to other sources. The first chapter, which is typical of the rest, is on the influence of X rays on living tissues and consists of 24 pages which cover an appended bibliography of something like 250 references; the authors are scrupulously careful to give credit to the correct source of every observation recorded. The sincere attempt to bring together the work of other people by this method has led to an uneven compilation with serious gaps. For instance, the account of embryonic development of the osseous system is most incomplete, and the authors give no description of their own investigations or determinations of the times of the appearance or union of the various epiphyses. The carpus is satisfactorily described, but only three bones of the tarsus are mentioned. Some of the statements are not clear; for example, the authors, quoting Pryor, say, "The epiphysis of the ulna shows ossification in the sixth to eighth year of the postnatal growth, and in the radius about the eighth to tenth month"—a sentence which implies either that these bones have only one epiphysis each or that the epiphyses at each end appear simultaneously. We can find no other reference to these important epiphyses.

We have, first, an account of the cardiovascular system as shown by means of radiograms of opaque injections, and a more complete description of the various congenital and developmental bony abnormalities. The second half of the book is devoted to the obstetrical uses of radiology, and a good account is given of the various methods of radiological pelvimetry and the X ray diagnosis of normal and abnormal pregnancy. The last 100 pages describe various monsters, many of which have been radiographed.

Those illustrations, which have been reproduced from published articles and not from originals, have lost much detail in the double reproduction. Those on pp. 68, 181, and 299, to give only three examples, are valueless. The illustration on p. 163 is upside down.

A compilation of this type, although it may contain a wealth of information carefully brought together and well indexed, inevitably lays itself open to criticism. Its merit is that anatomists, radiologists, and gynæcologists will find in its pages information difficult to obtain from scattered literature and, on the whole, well epitomised. This purpose would have been better served had the authors given the titles of the articles that are quoted in the bibliographies at the end of each chapter.

THE SURGICAL TREATMENT OF SPINA BIFIDA.

Zur Bewertung der chirurgischen Behandlung der Spina Bifida. By Dr. KARL M. STOCKMEYER, Basel. Berlin: S. Karger. 1926. Pp. 46. M1.80.

THIS slender monograph is based on some 42 cases from the records of the Children's Hospital in Basel, and on 171 cases from the literature, a total of 213. Numerous tables are given of the results of operation in the different types, the following being considered separately: meningocele, myelocystocele, meningomyelocele, meningomyelocystocele, and spina bifida cystica. Head, cervical, dorsal, lumbar, lumbosacral and sacral varieties are distinguished. Details are given of operative procedures. Slight though it is, the book contains a singularly complete investigation of a subject that has been rather neglected, and may conceivably serve to modify the pessimistic view usually taken of the treatment of these congenital malformations. As it is, the figures given by Dr. Stockmeyer are depressing enough: mortality-rate of all cases operated on, 46 per cent.; improvement or cure of existing paralyses, 3·9 per cent.; stationary condition after operation, 79·8 per cent.; aggravation of symptoms after operation, 16·2 per cent.

MODERN OPHTHALMOLOGY.

A Practical Treatise on the Anatomy, Physiology, and Diseases of the Eye. Fifth edition. Revised, enlarged, and rewritten. By JAMES MOORES BALL, M.D., LL.D., late Ophthalmic Surgeon to the St. Louis City Hospital. Philadelphia: F. A. Davis Company. 1926. With 598 text illustrations and 24 coloured plates. Pp. 721.

THE first edition of this work appeared in 1904 as a volume of 820 pages. This fifth edition is practically a new book, most of the chapters having been rewritten and much material added. The work is now bound in two volumes, each being about the size of the original one. Several well-known ophthalmologists have coöperated in the production of the work, and the result is a complete text-book of the embryology, anatomy, physiology, and diseases of the eye, which can hold its own in comparison with other first-rate text-books on a similar scale, such as those of Fuchs and de Schweinitz. This edition is dedicated to the Ophthalmological Society of the United Kingdom, of which the distinguished author has lately become a member, and there are several references to the recent work of British ophthalmologists. It is, of course, impossible to make a text-book really exhaustive. For instance, the anatomy of the ciliary region is given in this book in considerable detail, including some of the sections published by Prof. Arthur Thomson. The functions of the ciliary muscle are less satisfactorily dealt with, and no mention is made of Thomson Henderson's researches on the subject. Again, the slit-lamp with binocular corneal microscope, which is now considered by several modern ophthalmologists as an essential part of their equipment, receives only cursory mention. There are certain inconsistencies in different chapters. In that on sympathetic ophthalmia the treatment by salvarsan is briefly noted. Under "salvarsan" in the chapter on therapeutics written by Dr. W. F. Hardy its use is said to have been followed by extremely satisfactory results, but in neither place is there any hint that success is dependent on the blood count. These examples are given only to show that it is well-nigh impossible for a large text-book to keep quite up to date. The most stimulating text-books are those which do not attempt to be exhaustive, but make apparent the personal message of the author.

Dr. Ball's work, however, is eminently readable and reliable. The print is luxurious and the illustrations excellent.

FACTS ON THE HEART.

By RICHARD C. CABOT, M.D., Professor of Medicine and of Social Ethics at Harvard University. London and Philadelphia: W. B. Saunders Company. 1926. Pp. 781. 35*s*.

To study the living rather than the dead has been the fashion of pathology in recent years, and the pathologist of to-day tends to frequent the experimental laboratory and the ward as well as the post-mortem room. That morbid anatomy correlated with clinical observations still affords a most fertile field for research must not be forgotten; this lesson, in its special application to cardiology, is exemplified in Dr. Richard C. Cabot's stimulating book. Dr Cabot has here followed the same attractive method which he adopted with so much success in the teaching of students, reasoning from the post-mortem to the clinical findings. His material consists of nearly 2000 cases in which the cardiovascular system was involved, in a consecutive series of 4000 autopsies performed at the Massachusetts General Hospital over a period of 23 years. Such a wealth of material provides much food for thought and speculation. The critical reader will not see eye to eye with the author in all his sweeping generalisations, but he cannot fail to be grateful to him for providing so many protocols, both clinical and pathological, copiously illustrated with beautiful photographs, radiograms, and charts. The facts are there, and on those facts the reader can base his own conclusions.

The common types of heart disease are rheumatic, syphilitic, and hypertensive. These three constitute rather more than 90 per cent., while acute and subacute endocarditis account for less than 10 per cent. of the cases in this series. From a pathological standpoint angina must be regarded as a symptom complex rather than as a definite entity, for it has no constant anatomical basis. The section devoted to hypertensive heart disease is of particular interest. In this group, which in numbers exceeds that of all other groups of heart disease put together, the author includes all cases of enlarged heart which were not associated with either chronic pericarditis or with any valvular lesion. He believes that the condition is essentially independent of both nephritis and arteriosclerosis. In only one-third of the hypertensive cases did death result from heart failure, while in the remainder it was due to cerebral hæmorrhage or to some intercurrent disease. Another lesion which frequently remained latent for 15 or 20 years after the original infection without producing symptoms was syphilitic aortitis, but after clinical manifestations made their appearance death usually followed within two years. Attention is called to the frequency with which both pericarditis and mitral stenosis are missed during life; while, on the other hand, it is surprising to find that in seven cases only out of the whole 1906 investigated was mitral incompetence present post mortem unassociated with stenosis. It was, in fact, one of the rarest of valvular lesions.

Dr. Cabot is inclined to be hard on the clinician, and we must hope that he is over-stating his case when he says that in his experience in most patients diagnosed as suffering from heart disease the heart is perfectly sound. Conclusions based on such an extensive research cannot fail to command attention, but the statements that myocarditis is not clinically recognisable, and that the sounds produced in pericarditis are indistinguishable from intracardiac murmurs, will not pass unchallenged. How far one is

justified in applying evidence derived solely from fatal cases to heart disease in general is an open question; but this doubt in no way detracts from the value of the observations recorded in Dr. Cabot's book, which forms a valuable contribution to our knowledge of cardiac pathology.

THE QUARTZ MERCURY-VAPOUR LAMP.

Its Possibilities and Uses in Public Health and General Practice. By J. BELL FERGUSON, M.D., D.P.H., Medical Officer of Health, Tuberculosis Officer, and School Medical Officer, County Borough of Smethwick. With an introduction by Sir HENRY J. GAUVAIN, M.A., M.D., M.C., Medical Superintendent, Lord Mayor Treloar Cripples' Hospitals. London: H. K. Lewis and Co., Ltd. 1926. Pp. 106. 6*s*.

THOUGH books on ultra-violet therapy are accumulating at a great rate there is plenty of room for one by Dr. Ferguson, who, as medical officer of health, tuberculosis officer, and school medical officer for the County Borough of Smethwick, has had excellent opportunities of seeing the beneficial effects of this form of therapy on the ailments for which it is suitably prescribed. He holds that for the man in general practice and for the busy medical officer of health the quartz mercury-vapour lamp is the only practical apparatus, and his remarks on treatment are restricted to this source of radiation.

The first two chapters are devoted to a brief historical sketch and to the physical, chemical, and physiological properties of ultra-violet radiation. Then follow chapters on technique, dosage, and the possible dangers of this form of therapy. The next section describes the actual working of a modern public health department, with details of the clinic, staff, and equipment necessary for its maintenance, while a discussion follows on types of disease met with in general practice which are benefited by ultra-violet radiation. The succeeding pages contain many useful hints to beginners, including a table of suggested initial doses suitable for a large variety of complaints.

The author is both critical and enthusiastic of the future of ultra-violet therapy, for on p. 98 he says: "Ultra-violet radiation should be available in every infant welfare scheme in every town. Prophylactic use of ultra-violet radiation in the first year of life would banish rickets, tetany, and spasmophilia from our infant population." It may be hoped that opportunity to test this optimism will not be lacking.

MEDICAL CASE-TAKING.

By ALEX. MILLS KENNEDY, M.D. Glasg., Professor of Medicine, University of Wales, and Director of Medical Unit, Welsh National School of Medicine, Cardiff. London: Edward Arnold and Co. 1926. Pp. 148. 5*s*.

Prof. Kennedy has written a guide for procedure at the bedside to help the clinical clerk entering upon his duties for the first time. We believe the book will be of service as a brief introduction to clinical work rather than as a guide-book to be carried round and consulted at intervals. It presupposes that a preliminary training in physical signs and laboratory methods has already been given; for this reason, doubtless, certain axioms have been omitted, but it is hardly safe to assume that the junior student has mastered the elements of clinical examination. Since Prof. Kennedy has produced a useful little book which should be popular among students in other schools than his own, where clinical instruction may not always precede ward work, it would be well, in future editions, to treat the reader as quite a beginner. In dealing with the heart the student is instructed to mark the position of the apex beat with a skin pencil; but no definition of the apex beat is given and he may possibly be confronted with a large area of apical pulsation and be unable to decide which point constitutes the "apex beat." For the rest, the book is well written, concise, and clear, and, on the whole, accurate. The author mentions Austin Flint's murmur (p. 78), but not Graham Steel's. In describing certain types of respiratory movement no mention is made of the "inverted" type frequently met with in children and only scant attention is given to the value of eliciting tactile fremitus in the examination of the thorax. In discussing the palpation of the spleen Prof. Kennedy states "when there is some slight enlargement the lower edge of the spleen may just be palpable below the costal margin." It is usually accepted that a palpable spleen is probably at least twice or three times the normal size. Among minor points calling for criticism is the printing of the symbol for hydrochloric acid as "H.Cl."

In these days when the student is much distracted from the wards by laboratory work, it is satisfactory to see that in our schools the foundations of clinical medicine are still well and truly laid.

THE MEDICAL DIRECTORY, 1927.

Eighty-third annual issue. London: J. and A. Churchill. 1927. Pp. cviii.+2163. 30*s*., post. 1*s*.

IN our office the advent of a new issue of the Medical Directory is hailed every year with satisfaction, for by the late autumn its predecessor, in spite of a stout binding, has become thumbworn and a little ragged. This is hardly surprising, for the book is more used than any other on our shelves. It is not insular prejudice that makes us prefer the scope and format of this Directory to that of corresponding publications issued in other countries; experience has convinced us that desirable information about doctors is given more clearly here than in most similar works, neither cross references nor a good memory for symbols and abbreviations being required. There are 1405 more names in the book this year than last, the increase being divided fairly evenly over the various sections except the Services, where the diminution which began in 1922 still continues. The accuracy of the list is very high, but we cannot help still regretting the absence of the asterisk which used to show so clearly which practitioners had failed to respond to requests to confirm the information and bring it up to date. In the list of Titles Conferred there are some trifling inaccuracies and one or two names whose bearers are deceased. A little space has been saved by omitting unnecessary details of London medical societies, but the list of coroners which has disappeared will be missed. We congratulate the Medical Directory on its eighty-third birthday and rejoice in the assurance that in spite of its years its circulation is unimpaired.

DISEASES OF THE EAR.

Hunter Tod's Diseases of the Ear. Second edition. Revised and largely rewritten by GEORGE C. CATHCART, M.A., M.D., Consulting Surgeon to the Throat Hospital, Golden Square. London: Humphrey Milford, Oxford University Press. 1926. Pp. 333. 10*s*. 6*d*.

As it is nearly 20 years since the late Mr. Hunter Tod wrote his excellent little manual on diseases of the ear, considerably more than a mere revision has been necessary in the preparation of a new edition. Dr. George C. Cathcart, who undertook the work and who has done it well, has rewritten portions of the book and rearranged a great part of it without materially increasing its size. After a short introduction on acoustics, he has brought the description of the anatomy and physiology of the ear together into one chapter; and this is followed by another on examination, including the testing of the auditory and vestibular systems. This is an improvement on the original scheme of the book, where these subjects were scattered through the various chapters on external ear, tympanic membrane, and middle ear. The account of the labyrinthine tests is particularly clear for so abbreviated a description. The book presents, in a brief and easily read form, just the information required by the practitioner.

THE LANCET.

LONDON: SATURDAY, DECEMBER 11, 1926.

EPSOM COLLEGE: THE NEW SANATORIUM.

WE publish to-day an appeal from Dr. RAYMOND CRAWFURD, the Chairman of the Council of Epsom College, for the provision at the school of a new sanatorium, with an isolation block attached. The existing sanatorium is, Dr. CRAWFURD says, and as the many doctors who have visited the school know, quite out of date both in the accommodation which it offers and in its arrangement, making it uneconomical in working while providing no proper facilities for the isolation of infectious cases. Having regard to the fact that Epsom College, which now takes its place among the large public schools of England, had its origin in medical enterprise, it is in a sense a reproach to the medical profession that the school, with which their interests are so closely bound up, should not provide, through its machinery for the maintenance of the health of its scholars, a model to other schools; it should be in a position to deal with accidents, with sickness, and with infections among its scholars on the most modern and efficient lines. But for material reasons it can do nothing of the sort. The school is healthy, and unremitting attention ensures that it should be so, but it is without the proper equipment for the purpose.

The provision of a new sanatorium and isolation block at Epsom College is, in fact, now a most pressing need, for the well-equipped isolation block, which is a necessary part of the sanitary accommodation of a public school to-day, is represented at Epsom by a wooden structure with a limited life. The authorities at Epsom appeal to the practitioners of the country to come to their assistance, but before doing so they have made a thorough and careful inquiry into all the circumstances. The experience of schools like to Epsom suggests that the main sanatorium should afford 20 beds, while the isolation block should contain 40 beds for time of epidemic. The medical officer of the College, with the aid of a distinguished hospital architect, has prepared outline plans for a model sanatorium and isolation block of this capacity, and the estimated cost of the new buildings, though economy has throughout been considered, is £25,000—£15,000 for the sanatorium and £10,000 for the isolation unit. This, of course, is a very large sum of money, and the appeal made in our columns concerns in its practical application a profession which cannot be called a lucrative one as a whole. It is true that a small gift—only 10*s.*—from every medical man on the Register would result in the immediate finding of the necessary sum, and considering the inclusive nature, from the professional point of view, of the benefits offered by the Epsom Foundation, it is right to say that the claim upon the members of the profession is also inclusive. There are excellent reasons why all should give in ratio to their ability. Free education to the needy sons of deceased or disabled medical men, and the provision of pensions to aged or infirm medical men or to the widows of medical men, form the objective of the Royal Medical Foundation. Those familiar with the business side of medical practice in this country—those who know its emoluments, its strains, and its risks from early disablement or premature death—realise fully that a great section of the profession and their dependents must be found every year in a position when the free education of a child is a boon beyond description in value, while the alleviation of more immediate distress, through pensions to aged doctors or the widows of doctors, may mitigate situations whose real character has to be known if their bitterness is to be appreciated. The Foundation, despite both general support by doctors, and many signal acts of individual generosity, has no pecuniary surplus whatever; its carefully husbanded money is all required to finance the educational and pension systems; thus Dr. CRAWFURD'S suggestion is a logical one that this great and necessary charge for the maintenance of the health of the scholars should be met in the medical profession by a self-imposed poll tax. But the thing that is logical is not always the thing that gets done, and, while we endorse heartily Dr. CRAWFURD'S plea for an immediate collection on a capitation basis, we agree with him that it would be idle to look only here for the large sum required.

Long division sums may suggest an answer to the problem on paper, but in fact, though much money, it is hoped, will be obtained from a mass of small subscriptions, individual donations of larger sums will be needed. It is fair to look to the public for assistance here, for Epsom College plays a great professional part, and the public freely acknowledges indebtedness to the profession. The College, although having a distinctive connexion with medicine, possesses a Foundation moulded on that of Eton or Winchester—that is to say, that, while the best facilities for the education of the scholars on this Foundation are provided, a welcome is extended, for the enjoyment of those facilities, to the children of parents who are able to meet the ordinary public school charges. Doctors are in a good position for bringing to the notice of all sections of the public—the wealthier sections as well as those less fortunate—the value of any public movement, and we cannot think of a direction for the pecuniary endowment of medicine that would be more highly appreciated by doctors than support for Epsom College in its efforts for the health and safety of the boys. The position of a medical man incapacitated or deeply impoverished, while his children are at an expensive school age, and equally the position of a widow of a medical man who has died before any opportunity of saving has occurred, are particularly pathetic. No words are needed to prove this, and a plea for subscriptions based on such facts would surely bring large returns if it were largely advanced. The authorities at Epsom, in recognising their responsibilities before any misadventures have brought them home, are taking a brave step. They must be supported.

THE CONTROL OF PERIPHERAL CIRCULATION.

THE nervous control of the peripheral parts of the blood-vessels which supply the skin and muscles of the limbs is undoubtedly very complex, but the clinical observations recently discussed at the Royal Society of Medicine (vide p. 1215 of this issue) make it desirable to consider what is known of it from physiological experiment. Surgeons report cases in which division of the nerve plexus around the main artery supplying a limb has been followed by an increase in the blood-flow through the skin of that limb, as shown by increased warmth and by flushing of the part, and this effect has been used with

variable success as a means of staving off gangrene. It is certain that in the absence of any change in arterial and venous pressure, increased blood-flow to any part of the body can only be brought about by arteriolar dilatation, and where the skin is flushed it is evident that there must be in addition a dilatation of the capillaries and small venules. If, indeed, these phenomena follow periarterial neurectomy it behoves us, if possible, to explain them in terms of our present physiological knowledge. Histological investigation has shown beyond dispute that the arterioles, and possibly the capillaries, are provided with both motor and sensory nerve-endings. Evidence of this was adduced by A. S. DOGIEL in 1898, but the function served by the afferent supply is still somewhat problematical. The efferent terminals are doubtless sympathetic in origin, and it is clear from the work of J. N. LANGLEY that the sympathetic effector neurons (the grey rami) run in the ordinary mixed nerves to the limb. LANGLEY isolated and divided the lumbar sympathetic in cats and stimulated its central end, at the same time observing the colour of the pads of the feet. This experiment was repeated after division of the anterior crural and sciatic nerves, and it was found that the reflex paling which occurred when the crural and sciatic nerves were intact was completely abolished after they had been divided. Taken together with the well-known fact that dilatation of the arterioles and capillaries follows section of these nerves, LANGLEY'S observation shows that the vessels are under the control of sympathetic fibres which run in the ordinary mixed nerves; this control is tonic in nature and is potentially influenced reflexly by afferent impulses from the limb through the sympathetic. Experiment, therefore, seems to negative the suggestion that increased blood-flow to the limb following periarterial nerve section is due to the removal of tonic vasoconstrictor nervous impulses running through this network to the periphery. Should the periarterial network contain a functional preponderance of efferent depressor fibres or of efferent sympathetic vasodilator fibres in a state of tonic activity—a supposition for which there is no experimental justification—section of the network would be expected to give rise to peripheral vasoconstriction.

It is clear, therefore, that a tentative explanation of the clinical phenomenon observed may be more hopefully expected if we direct our attention to the possibility of the nervous network containing afferent fibres. If we may assume for the moment that it does—a possibility which was suggested by LANGLEY in 1923—it seems that the vascular dilatation should be interpreted as being due to the removal of afferent impulses having an excitor action on the local spinal vasoconstrictor centre, or an inhibitory action on the antagonistic vasodilator centre, or a combined action on both. The fibres concerned would thus be afferent pressor in nature. That such fibres exist in the lumbar sympathetic is shown by the experiments of LANGLEY already referred to, experiments which are analogous to those of SHERRINGTON, who found that a reflex rise in blood pressure in the spinal animal was produced by stimulation of the central end of the cut splanchnic nerve. Afferent pressor fibres certainly run in the ordinary mixed nerve-trunks along with depressor fibres, as can readily be shown experimentally by using different modes of stimulating the central ends of the divided nerve. As W. M. BAYLISS remarked, it may be that the depressor fibres in ordinary nerves are afferent fibres from arteries, and are analogous to those of the depressor nerve. He himself showed that section of the depressor in the rabbit is occasionally followed by a rise in blood pressure, and it is to be supposed that if the afferent depressor fibres from the limb vessels could be severed independently of the afferent and efferent pressor fibres, a local vasoconstriction would result. Conversely, section of the afferent pressor fibres would be calculated to produce a local reflex vascular dilatation.

On the hypothesis, therefore, that in the operation of periarterial neurectomy afferent pressor fibres are divided, the resultant effects receive a presumably adequate interpretation. The efferent path would probably be both through the sympathetic—assuming that the tonic impulses passing down it are inhibited—and through the antidromic nerves, whose centres are assumed to be stimulated. We should, therefore, obtain, on the one hand, arteriolar dilatational (sympathetic inhibition), and, on the other hand, dilatation of the capillaries and the small venules in the skin, the latter effect being brought about by the setting free of metabolites by the antidromic nerve-endings, as suggested by LANGLEY. It will be apparent that the interpretation given above of the clinical results contains an undesirably large proportion of hypothesis to fact, and it is equally clear that a complete histological and experimental investigation of the origin, course, and functions of the nerve-fibres found in the periarterial network is urgently required.

SOCIAL REVOLUTIONS AND THE PUBLIC HEALTH.

THE concern widely felt as to the declining birth-rate in this country, with the prospect of a corresponding decline in the actual population, seems to indicate that a rising population is accepted as a good thing in itself. It is true that an increasing body of sociologists are harking back to the doctrines of MALTHUS, and urging the restriction of births as one solution of our post-war problems. It is equally true that some of those who deplore the prospect of a stationary or falling population do so not because they consider the tendency disastrous in itself, but rather as an unfailing index of declining national prosperity and also because of its selective action. The question whether the growth of the population which accompanied the industrial revolution was due to an increase of the birth-rate or any other cause is therefore worthy of attention. We have become so accustomed to the abundant statistical data supplied by various Government departments, that the inquirer who turns his attention to the question of population for the first time is a little surprised to find that the available information on the subject up to the end of the eighteenth century is largely the result of guess-work. In spite, however, of considerable differences in the estimates of different authorities, there can be little doubt that the growth of population in England and Wales in the Middle Ages, although more or less continuous, was very slow. While the population nearly quadrupled itself in 100 years between 1801 and 1901, it took 700 years up to 1760 to accomplish little more than the same proportionate increase. The rate of growth was somewhat accelerated in the eighteenth century, towards the end of which those factors had come into play which accompanied the phenomenal expansion of the nineteenth century.

In tracing the growth of population in the eighteenth century we are largely dependent on such records as exist of the births and deaths which occurred. Curious discrepancies arise from differences of interpretation. Thus, Miss BUER in her recently published work [1] accepts as established an increase in the population of London during the period 1750 to 1801 from 676,000 to 900,000, which she attributes mainly to the falling death-rate. She quotes SHORT'S estimate of the death-rate of London in 1750 as 50 per 1000. According to FARR,[2] who accepted estimates by SIMPSON and PRICE for the earlier periods, the mortality during the non-epidemic periods 1728–37 and 1771–80 was 52 and 50 respectively, but fell to 29·2 in 1801–10. BROWNLEE,[3] on the other hand, confining his attention to the area of the Bills of Mortality of London, and judging by the number killed, the number dying over 60 years of age, and the numbers of abortions and stillbirths, considers that certain quoted estimates of the population showing little increase are justified. He calculates a series of death-rates rising to 37·8 per 1000 in 1721–30, and falling thereafter more or less steadily to 26·9 in 1791–1800. His estimate of the death-rates for periods closely corresponding to those for which FARR thought the rates were around 50 per 1000 are 36·2 and 29·5 respectively. Such rates are obviously of a different order, and it is hard to believe that the discrepancies can be due to the difference of area covered by the Bills of Mortality and London proper. Nevertheless, it appears to be agreed that the death-rate, probably stationary until the eighteenth century, did fall during its greater part, and there is no difference of opinion as to the remarkable decline of infant mortality which took place after the middle of that century. Taking into account a fairly stable number of births, as shown by the Bills of Mortality, the saving of lives, especially among infants, must have been followed by an increase of population which probably found living-room for itself outside the area of which these Bills are the records. There is good ground for believing that the same process was at work all over the country.

This rise of population and the falling death-rate to which Miss BUER attributes it form the text of an interesting survey in her book of the conditions of life in England and Wales in the early days of the industrial revolution from 1760 to 1815. The influence of new ideas in agriculture and market-gardening, new discoveries in industry, progress in medical knowledge and practice, the hospital and dispensary movement, improvement in sanitation and especially in water-supplies, the benefits of inoculation and vaccination are all shown to have raised barrier after barrier against disease at a time which has been impeached as the source of many of the evils that faced the Poor-law Commissioners in and around 1830. So far from being a period of deterioration, Miss BUER shows that the rise of industrialism and its attendant prosperity were mainly instrumental in bringing about an improvement in the health of the people and in their well-being. This is a useful contribution to our knowledge of a period, the circumstances of which have been somewhat overshadowed by the more striking episodes of the post-war times dating from 1815, when unemployment, industrial reorganisation, and cholera epidemics combined to create an impression of the influences of industrialism in harmony with its blatant ugliness. Cholera epidemics were probably no more the result of the rapid growth of towns and overcrowding, than influenza in 1918 was due to the Great War, or the Black Death to any new world movement, or the long waves of measles to circumstances over which human effort has any control. If cholera had come earlier it could scarcely have failed to spread under social and environmental conditions which were even worse than those of the industrial era. On the other hand, one direct result of industrialism and the growth of towns was an increase in the mortality from tuberculosis almost certainly due to the influx of "unsalted" rural dwellers, many from the Celtic fringe, into surroundings woefully suited for the transmission of infection. It is easy to postulate a somewhat similar explanation of the typhus epidemics. After all, the real industrial revolution of steam motive power and machinery had scarcely begun until 1815, and its evil results were not to be looked for till about that time.

There can be little doubt that post-war social distress, followed by rapid urban expansion and improvements of transport, created conditions favourable to the spread both of endemic communicable disease and also of accidentally introduced epidemic infections. A certain resemblance between present-day circumstances and those of 100 years ago—the trade slump following the vigorous industrial development of war-time, unemployment, a lavish Poor-law, fulmination of the comfortable against disgruntled and unaccommodating workers, increased employment of women in industry and commerce, and the radical reorganisation of industrial methods which appears to be impending—may reasonably awaken forebodings of evil so far as the health of the people in the near future is concerned. It is true that the last eight years have seen a rapid fall in the mortality from most forms of disease. There appear, however, to be signs that the decline of tuberculosis is slowing. When we remember, too, that the air-borne infections which we are least able to control, such as influenza, encephalitis, and poliomyelitis, have shown a tendency to fresh vitality in recent years, and that the prevalent overcrowding in dwelling-houses must be favourable to their spread, the possibility of a period of public health retrogression is not entirely remote among that section of the people whose standard of living is gradually being lowered.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—On Thursday, Dec. 16th, at 5 P.M., Mr. Ernest Clarke will lecture on Emergencies in Ophthalmic Practice, at the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, W. This lecture is free to members of the medical profession. A further series of lectures in Emergencies in Medicine and Surgery will be held from January to March, and there will also be a series of clinical demonstrations in ophthalmology and surgery. The Queen Charlotte's Hospital offers practical courses in obstetrics lasting from two to four weeks. Weekly courses in obstetrics and child welfare are undertaken by members of the staff of the City of London Maternity Hospital. The Fellowship can also arrange clinical assistantships at the Samaritan Hospital. The following special courses will be held in January: A fortnight's intensive course in medicine, surgery, and the specialties at the Prince of Wales's General Hospital from Jan. 10th to 22nd; a fortnight's all-day course in cardiology at the National Hospital for Diseases of the Heart, for which the entries are limited to twenty, from Jan. 17th to 29th; a fortnight's course in diseases of children at the Royal Free Hospital and the Children's Clinic, from Jan. 10th to 22nd; a month's course (Tuesday and Saturday mornings at 11 A.M.) in psychological medicine at the Bethlem Royal Hospital from Jan. 11th to Feb. 5th. Copies of all syllabuses of the special courses, of the general course programme, and of the *Post-Graduate Medical Journal* may be had from the Secretary of the Fellowship, at 1, Wimpole-street, London, W.1.

Annotations.

"Ne quid nimis."

THE USE OF PHOTOGRAMS.

ONLY the most original minds can venture to publish the results of their investigations without having a care first to discover what has been already written on the matter to be investigated. For this purpose nothing can adequately take the place of personal search at a well-equipped reference library, but time and distance make this difficult in many cases, and the library of the Royal Society of Medicine has long offered special facilities to its members who live abroad or at a distance by supplying extracts of articles and bibliographies on specific subjects. There are obvious limitations to vicarious reference, and it is somewhat surprising that little use has been made in this country of the photostat which produces on demand copies of articles with their charts, tables, and illustrations in facsimile. The library of the College of Physicians in Philadelphia installed such a machine some 10 years ago to supply Fellows of the College with replicas of pages in books and of articles in journals at a cost in many cases less than that of postage of the original to and from the worker. Use was made of the Philadelphia photostat by applicants in all parts of the United States and even from Great Britain and Germany, and similar facilities have been provided in Washington and Stockholm. The library of the British Museum has recently installed an official photostat, of which readers make great use, finding a photostat copy cheaper than one made by hand. The minimum charge is 1*s.* each for a negative (white on black) 11 × 7 in., a positive (black on white) costing double. Apart from this everyday use the photostat can reproduce completely, and so render more accessible the rare volumes which no library is willing to circulate through the post. The reproduction may have an almost uncanny accuracy and throw off their guard any except the most wary reader. Where permanency is desired it is well to insist on the print being made on bromide paper. The Central Depôt for Scientific Information in Berlin (Unter den Linden 38, Berlin, N.W. 7) now announces that it is in a position to supply reproductions of original scientific literature in its own and other languages in the form of photograms. The price of these for teachers and students has been fixed for the present at 4 pf. per square decimeter—i.e., about 4 in. square—to cover the actual cost, the price for business purposes being 7 pf. Orders should give exact information in the following sequence: author, title, source of original text, kind of photogram desired, whether in the original size or reduced. The price to students appears to work out at the astonishingly low price of about ¾*d.* for a column the size of our own, but it is not specifically stated whether the price relates to the size of the photogram or the size of the article from which the reproduction is made. As this process has already proved really helpful to scientific students, it is to be hoped that its utility will soon be recognised by one or other of the medical libraries in this country, and that the price charged for copies may follow the Berlin example. The danger of the photostat lies in this—that for the sake of economy the purchaser or correspondent obtains a copy only of what appears to him to be the vital paragraph and may lose an equally vital context.

ACIDOSIS AND INSULIN.

POST-OPERATIVE acidosis has long presented an unsolved problem. Both the origin of the harmful acids and the extent to which they are injurious remain uncertain. There is also the problem of the ketone bodies and of those cases of post-anæsthetic toxæmia in which the alkalinity of the blood is diminished without there being any evidence of excessive acidity, or of the presence of acetone, diacetic acid, or ketone. All these conditions are often loosely referred to as acidosis, although it would be better to use the term only where there is actually excess of the acid bodies—not merely diminution of the blood bicarbonate. The two conditions in which these blood states are most prominent are post-anæsthetic toxæmia and the uncontrollable vomiting of pregnancy. The former has lately been investigated afresh by M. Labbé and M. Chevki,[1] and the latter by H. Seidl.[2] The French writers arrive at the conclusion that post-operative ketosis depends on a nutritional disturbance, caused by the anæsthetic, in which functional inefficiency of the liver plays a large part. This is, of course, in line with the theory usually accepted, although it leaves unexplained the occasional appearance of the symptoms after local anæsthesia, and, indeed, after shock independent of any anæsthetic. General interest in the treatment of acidosis has been aroused by the introduction of insulin. On the grounds that there is a pathological analogy between the metabolic defects which lead to acidosis in diabetes and those which cause it after operations or during pregnancy, it is argued that insulin should be used in the treatment of post-anæsthetic toxæmia and the hyperemesis of pregnancy. Seidl claims good results in seven cases of hyperemesis treated, and believes that insulin should be employed in all patients in whose urine ketone bodies are present. The French observers similarly recommend the use of insulin in the post-anæsthetic patients in whom there is not merely diminished alkalinity of the blood, but actual acetonæmia or ketones or extra acids in the urine. The use of insulin after operation has been much advocated in America, but, as we have pointed out,[3] the Toronto group in 1924 stated that "it is difficult to see what purpose it could serve," and cast doubt on the value of insulin "in conditions other than those in which there is a distinct deficiency of insulin metabolism." Insulin, they remarked, is a powerful drug, and should not be used recklessly. The question is to be brought before the Section of Anæsthetics of the Royal Society of Medicine during the current session.

HYDRATED MORPHINE DERIVATIVES.

So little is known of the intimate nature of drug action that it is almost always impossible to foretell at all accurately what will be the result of any chemical substance of known constitution coming into contact with a single isolated reactive tissue. And, of course, it is even harder to foretell the action of drugs on particular functions embodied in the coördinated complexity of the higher forms of life. Experiment, therefore, is the only means at our disposal by which to extend our knowledge of pharmacology and therapeutics, and one of the ways in which progress may be made is by the synthesis and study of derivatives of chemical substances which evoke a known biological response. The action of most drugs on man is by no means localised to the particular tissue whose function we may desire to stimulate or depress. If it were, the foreground of therapeutics would be much more easily penetrable than we find it. It may be hoped, however, that close coöperation between the organic chemist, the experimental physiologist, and the scientific clinician will give us chemical substances whose actions are more elective and which are thus of greater value in the treatment of disease. Advance along these lines must inevitably be slow, but a grain of sound experimental fact is worth infinitely more than a mass of hypothesis based on uncontrolled observation.

The hydrated derivatives of morphine deserve more intense study than they have received, and it is satisfactory to see an account of them contributed by Prof. Erich Leschke to an interesting volume which the firm of Messrs. Knoll and Co. has published to commemorate its fortieth anniversary. The derivatives chosen for investigation were Paracodin (dihydrocodeine), Paramorfan (dihydromorphine), Dicodid (dihydrocodeinon), Dilaudid (dihydromorphinon), and Eukodal (dihydrooxycodeinon). Dihydrocodeine is

[3] THE LANCET, 1926, i., 987.

found to be much more active in depressing the coughing reflex than codeine, which, as is well known, is itself relatively more active in this respect than morphine. Dihydrocodeine is also more specifically analgesic than morphine, in that the higher centres of the brain do not show that general depression characteristic of the action of morphine, and its constipating action is much less marked. It may be given by the mouth or subcutaneously. The pharmacological action of dihydrocodeinon occupies a position between those of codeine and dihydrocodeine. Its toxicity is approximately the same as that of morphine, but increasing tolerance is not nearly so marked as with the latter drug, a fact which, according to Leschke, can be readily shown in animal experiments. Dihydrooxycodeinon is more nearly allied to morphine in its pharmacological effects in that its general narcotic properties are well marked; indeed, in this respect it is relatively more potent than morphine, and it has been used successfully in biliary and renal colic. Dihydromorphine has a similar action to that of morphine, but the effect lasts longer and the degree of tolerance developed to repeated injections is said to be decidedly less. Dihydromorphinon exerts its narcotic and respiratory depressant action in doses one quarter to one half that of morphine. Tolerance to the drug appears much less readily, its action on the gut is extremely small, and the danger of habituation is very much reduced. It is clear that if this information can be confirmed and extended by further experiment it must be recognised as a valuable contribution to pharmacology and therapeutics.

POISONS IN SHELL-FISH.

ARSENIC, as was shown in the notorious Manchester beer epidemic, has a way of cropping up in strange places. It has been found, for instance, in certain medicinal preparations of seaweed, notably Irish moss or carragheen, and now Mr. A. Chaston Chapman, F.R.S.,[1] has discovered quite a lot of it in some of the marine crustacea and shell-fish. For purposes of investigation Mr. Chapman estimated the arsenic as parts per million of arsenious oxide in the wet substance. In oysters from British beds this figure was in the region of 6, but in foreign oysters it was sometimes as high as 70 parts per million. In mussels the amount was even greater, sometimes reaching nearly 120 parts per million, a fact which may explain the poisonous symptoms which often follow the eating of mussels and are usually attributed to a poisonous alkaloid called mytilotoxin. The flesh of lobsters, both before and after boiling, yielded about 100 parts per million, but the highest quantity of arsenic, 174 parts, was found in some samples of prawns; this corresponds to over a grain of arsenious oxide per pound of wet edible flesh. Analysis of the sea-water in certain situations has led Mr. Chapman to conclude that "whatever may have been the original source of the arsenic, it is from the sea-water that the organisms dealt with in this communication have derived the arsenic they contain." It is obvious, however, that the arsenic can scarcely exist in any simple form in such quantities as that noted in the sample of prawns, for, if it did, toxic symptoms would be much commoner than they are. As a result of experiment it is thought that the arsenic compound present in the lobster, for example, is a more or less complex organic substance or mixture of substances soluble both in alcohol and in water. Examination of the urine of a person who has been eating shell-fish or crustacea has shown that the greater part of the arsenic is excreted in the urine soon after the food is taken. Nevertheless this would not necessarily prevent the occurrence of acute poisoning, and the problem arises how such quantities of arsenic are prevented, by chemical or physical combination, from exerting toxic effects. It is stated that this problem is being investigated. In the course of the analyses necessary for the determination of arsenic it came to light that in crustacea and mollusca there are also appreciable amounts of lead and copper. The latter is, of course, present in hæmocyanin, a blood-pigment of many invertebrates. It is also surprising to learn that formaldehyde has been found in certain kinds of fish, but Mr. A. R. Tankard and Mr. D. J. T. Bagnall [2] throw some doubt on the technique of this discovery, and at present formaldehyde cannot with any confidence be blamed for poisoning fish-eaters. If it is indeed the arsenic in oysters that is responsible for symptoms it is hard to see how untoward incidents can be prevented. Recent work in America[3] has gone to show that if oysters are contaminated with typhoid bacilli and returned to their natural waters they free themselves from infection in less than 16 days. This shows their excellent intentions, but it is scarcely likely that they could ever be trained to get rid of their arsenic as well.

THE THERAPEUTIC USE OF GOLD SALTS.

KRYSOLGAN and sanocrysin have in turn so completely occupied the field in the treatment of tuberculosis during the last few years that we are inclined to forget that the therapeutic use of gold salts is at least as old as Paracelsus. Almost every salt of the metal has been used and almost every disease treated with it. In a recent review Prof. Felix Klemperer and Dr. Alfred Salomon [4] have surveyed the whole field. The modern study dates from 1890, when Koch demonstrated that the growth of tubercle bacilli was inhibited by salts of this metal. Numerous investigators followed, most of them using the cyanides of gold, whilst Bettmann ingeniously tried combining them with tuberculin. Buch and Glück in 1911 introduced a combination of gold and cantharidin, and this was followed by an extensive series of experiments in Germany with the use of various gold cyanide and cantharidin preparations, some of which, such as aurocantan, have received special names. Then followed the work of Feldt with a combination of weak alkalis and complex organic salts of gold, resulting in the discovery of krysolgan and sanocrysin. The mechanism of action of these numerous gold preparations, from the early cyanide experiments to the most recent sanocrysin tests, is obviously far from being properly understood. One fact seems to stand out clearly: the action is not that of a direct destruction of the individual tubercle bacillus, but rather some action of the stored gold salt upon the tuberculous tissue liberating a product which for want of a better name has been called by many workers tuberculin. The use of this term is unfortunate, since there is no evidence that this substance is identical with the exotoxin or endotoxin of tuberculin. At best the assumption is an analogy. Those engaged in the treatment of cases will appreciate the pains which Klemperer and Salomon have been at to collect clinical records from various sources dealing with four of the most recent organic gold preparations—krysolgan, triphal, aurophos, and sanocrysin.

Amongst the numerous investigators who are now publishing their first results of the treatment of tuberculosis with sanocrysin Dr. Knud Secher [5] is entitled to speak with authority, since he was one of the early experimenters associated with Prof. Mollgaard. Dr. Secher remarks early in the book that although "complete sterilisation against tuberculosis" in man—in other words, the destruction of all living tubercle bacilli in an infected person—should presumably be possible, on the analogy of the animal experiments, yet such a result is not desirable. We are inclined to doubt whether such "sterilisation" (the word is hardly, perhaps, admissible to general usage in this sense) is even possible—at any rate by therapeutic treatment—in the majority of cases. But the writer's aim of "clinical restoration as nearly as possible" leaving the small remnants of infection to act as a focus of immunisation is an ideal not only

[5] Treatment of Tuberculosis with Sanocrysin and Serum. By Dr. Knud Secher, Physician in Chief to the Municipal Hospital, Bispebjerg, Copenhagen. London: William Heinemann (Medical Books). 1926. Pp. 256. 21s.

for those who use sanocrysin, but for all who treat tuberculosis. Dr. Secher follows the classification of tuberculosis into the anatomical forms of exudative, degenerative or necrotic, and productive or proliferative, which has now passed into common use on the continent, admitting that in practice it rarely gives a true picture of the clinical condition. The choice of case for sanocrysin treatment is probably best made on purely clinical grounds of history, signs, and symptoms, with a good radiogram as a backing, and without reference to a supposed pathological picture which may or may not exist. To the actual administration of the drug Dr. Secher finds three useful guides—temperature reaction (four types are recognised), erythema, and albuminuria, and he devotes a chapter to an analysis of all the untoward symptoms met with by various investigators. He agrees that it is not always easy to differentiate between toxic symptoms due to the gold-ion and those due to the liberation of tubercle endotoxin. Possibly the former may be more easily detected now that minute quantities of gold can be estimated in the urine and fæces by colorimetric, electrolytic, or iodometric titration. Although most English workers appear to have discontinued its use, Dr. Secher is a firm believer in the value of antiserum combined with sanocrysin, as originally advocated by Mollgaard. The interest in tuberculosis antiserum revived by sanocrysin investigation may itself lead to useful results. Dr. Secher adheres also to the large-dose method of administration, never using less than 0·5 g. as a start, and aiming at a high concentration of sanocrysin, being guided subsequently by the patients' reactions. Sanocrysin is a powerful drug, and cannot be used without facilities for careful observation of patients at rest in bed and without expert nursing. There is no question of ambulant treatment as in the case of tuberculin. All the necessary precautions have been taken by Dr. Secher, and his records, given in full detail in the book, are a monument of painstaking research. Of the ultimate results he is evidently convinced, for writing of pulmonary tuberculosis he says: "Sanocrysin treatment (when employed in accordance with right indications and carried through with sufficient energy) will in all patients cause an improvement of their condition and will cure a large number. . . ." Dr. Secher has had an extensive experience of sanocrysin and writes with conviction, but his readers may be more reserved in their conclusions.

SPIDER BITES.

IT is well established that some tropical spiders are big enough and poisonous enough to catch and kill animals as large as small birds. But modern observation has wiped out the tarantula myth, nor are there now found in Gascony "spiders of that virulency that, if a man tread upon them, to crush them, their poison will pass through the very soles of his shoes" as was once affirmed, Indeed, the pendulum has swung so far the other way that arachnologists have come to doubt whether spiders' bites ever cause illness in man. However, Dr. Emil Bogen, of Los Angeles,[1] has seen 15 cases in recent years where a characteristic chain of symptoms has followed the bite of *Latrodectus mactans*, a big black spider which has an unfortunate habit of lurking under the seats of privies. The chief symptom is pain, which may occur in any or every part of the body, irrespective of the site of the bite, and is accompanied with restlessness, nausea, dizziness, and other general signs. It is obvious from his description that the patient's complaints might easily be put down to fright if only an odd case was seen; they are, however, repeated with considerable regularity in all the examples which have come to the Los Angeles General Hospital. The pain is often very severe, and requires large doses of opiates to control it. Dr. Bogen has had good results by injecting the serum of convalescent cases. After a few days the patient recovers without any ill-effects. The bibliography is, unfortunately, not printed in the *Archives* "on account of lack of space," so that it is difficult for anyone who is interested to follow the matter up; but in his summary of the literature Dr. Bogen points out that similar poisonings, often from other species of *Latrodectus*, have been repeatedly described in Southern Europe, Russia, Australia, New Zealand, Madagascar, and South America, and there is evidently no reason to doubt that human arachnidism is a reality.

ROYAL MEDICAL BENEVOLENT FUND: THE CHRISTMAS GIFTS.

IT has been the practice of the Royal Medical Benevolent Fund for many years to present to the annuitants and some of the most necessitous grantees a Christmas gift. The Treasurer now makes an appeal for £370 to keep up this practice. The committee has not in hand any special fund to draw upon to meet this Christmas gift. The individual sum given, 25*s*., is small, but the recipients are many; in former years they have received this little augmentation of their narrow means and are no doubt looking forward to its receipt this year. It is a friendly act on the part of the managers of the Fund which should not be allowed to cease, and we trust that our readers will make the continuance possible by finding the small sum necessary. Subscriptions may be sent to the Hon. Treasurer, Sir Charters Symonds, at the Offices of the Fund, 11, Chandos-street, Cavendish-square, London, W. 1.

MEDICAL SUPPLIES IN WAR.

THE military authorities of the United States of America are clearly determined not to be caught napping by another war. All officers of the Medical Reserve are told precisely what will be their appointments on mobilisation, whether to hospitals, field ambulances, or as specialists. The question of medical supplies and their replacement is being carefully considered, and so far as surgical instruments are concerned, is discussed by Major R. C. Heflebower, Medical Corps, U.S. Army, in an address to the American Surgical Trade, reported in the *Military Surgeon* for November. The arrangements for providing instruments in war-time are in the hands of a special section of the Surgeon-General's Office, a section which has nothing to do with the present supply. First the section has to decide what instruments will be wanted, and what specifications shall be put forward; it is advised by certain Reserve officers, who are surgical instrument-makers, so that buying shall be done commercially in the best way. Then the quantity of stores wanted must be defined. Ultimately that will be settled by the scale of mobilisation, but at present tentative contracts are put out, and the tenders are advised upon by the Reserve officers, who discuss whether they can be better assigned — whether, for instance, similar contracts for forceps should be given to each contractor, or whether all large forceps should be made by one and all small forceps by another. The third question is, whence shall the instruments be obtained? At first some can be purchased; this will be the work of the Reserve officers, who (having regard to the needs of the civil population) will buy what is immediately available. The rest must be made. The industry, however, may not itself be able to cope with the demand, and it may be necessary to call on workers in associated trades. Thus surgical needles or scissors might be roughed out by other workers and finished by the surgical instrument-makers provided that there were enough skilled mechanics. So as to avoid a shortage the trades can get a lien on the services of mechanics engaged elsewhere, and these men will be scheduled as indispensable. Moreover, the raw material, power, and transport required for this work must all be arranged for in advance by the Assistant-Secretary for War, in the light of the needs of other essential services. It is hoped that working along these lines there will be little industrial confusion in the change from peace

to war, and that the Army will never be held up for expected supplies. The section has also in mind the danger of accumulating a large surplus of stores which, if thrown on the market, must disorganise industry in the difficult post-war days. Such foresight is astonishing.

A VACCINATION INQUIRY.

IN an address delivered before the Berne Medical Club, Dr. A. Hauswirth,[1] the medical officer of health for that city, reports that a committee consisting of two medical men, including himself as chairman, and three laymen, one of whom was an antivaccinationist and the other two opponents of all compulsory measures though alive to the advantages of vaccination, was appointed by the Berne City Council to inquire into the supposed evil effects of vaccination among approximately 40,000 persons who had been compulsorily vaccinated between the spring of 1922 and the autumn of 1924 on the occasion of a small-pox epidemic. Only 14 cases in all were reported to the committee which after a careful investigation found that there were only four cases in which a possibility or probability of a connexion between the disease and the previous vaccination could not be excluded. The first case was that of encephalitis lethargica in a youth aged 17, who developed the symptoms shortly after vaccination, and made an almost complete recovery. The second case was one of fatal septicæmia following measles which occurred in a girl aged 9 years, vaccinated on the third or fourth day of the incubation period. In the third case a girl aged 14, six days after vaccination, developed follicular tonsillitis, followed by fatal septicæmia. The fourth case was that of a boy aged 13, who was vaccinated six days after recovery from an acute gastro-intestinal attack, accompanied by circulatory disturbance. About a week later symptoms of acute septicæmia developed, and death took place. The three deaths, therefore, were due to septic processes, in which the onset of the disease probably coincided with the performance of vaccination. The lesson to be learnt from these cases is that on the slightest suspicion of an acute infective or other acute disease vaccination should not be performed. In conclusion, Dr. Hauswirth remarks that as in only 0·01 per cent., or in 1 out of 10,000 vaccinations, could any evil effect be attributed to the process, the occurrence of such cases is far outweighed by the enormous benefit conferred by the absolute protection against small-pox provided by vaccination.

SAPONIFIED TOXIN IN SCARLET FEVER.

Prof. W. P. Larson, of Minnesota University, attended a meeting of health officers of the State of Ohio in the middle of last month, and gave an account of his method of detoxicating toxin and the results which he has had in producing active immunity against scarlet fever and diphtheria. Two years ago he was investigating the cause of pellicle formation in bacterial cultures, and to test his theory that surface tension rather than the presence of oxygen is the determining factor in this phenomenon, he introduced soap solutions into the culture media. Finding the appropriate concentration of soap, he was able to make all pellicle-forming organisms grow either in the liquid medium or at the bottom of the flask. The critical surface tension above which pellicle formation will always occur he found to be 42 dynes. Non-pellicle formers can be made to form pellicles if they will grow on a glycerine medium, and convert the glycerine into fatty bodies. Incidentally he observed that the tubercle bacillus loses its pathogenicity when grown on low-tension media instead of as a pellicle, and he claims that by using a medium containing soap he can produce in a few days cultures similar to the B.C.G. cultures which Calmette obtains by growing tubercle bacilli in bile medium for 13 years. The soap found most suitable as regards viscosity is a highly purified castor oil soap. These experiments led Prof. Larson to investigate the possibility of obtaining non-pathogenic strains of other bacilli. He was able to give detoxicated pneumococci to rabbits in doses which would have been certainly lethal without the admixture of soap, and he even succeeded in immunising guinea-pigs to tetanus, at the same time bringing evidence to support Ehrlich's theory that the more sensitive an animal is to a given toxin the greater will be its antibody formation in response to that toxin. All bacterial toxins, he found, can be detoxicated by this method without losing their immunising property, the only exception being that produced by *B. botulinus*. The first human volunteers were treated with a 1/10 L. + dose of diphtheria toxin in 1 per cent. castor oil soap, but it was found that the same dose in 2 per cent. soap gave less reaction. The latter mixture was used on 800 medical students, and over 60 per cent. of Schick-positive reactors became Schick-negative within 10 days. Applying the same principle to scarlet fever toxin (Dick), he found that a 3000 skin-test dose could be covered with 2 per cent. soap. This solution causes some reactions in adults, for whom a 3 per cent. soap solution is found to be more satisfactory. This dose immunises 90 per cent. of positive reactors within three weeks, and has been used as a prophylactic in various institutional outbreaks, apparently with success. As a method of prophylaxis it has none of the unpleasant concomitants of passive immunisation with Dochez serum. More recently a combined scarlet fever and diphtheria saponified (3 per cent.) toxin has been used; this is said to cause less reaction than the separate use of two saponified toxins. It should be added that Prof. Larson has been able to recover the toxin from his solutions by adding a simple salt solution, and has thus satisfied himself that there is no truth in the suggestion that the toxin is destroyed by soap. At present he recommends that two doses of the combined toxins be given at an interval of two to four weeks. Five thousand school-children in Minneapolis were given the first dose recently, and there was only one complaint—of a sore arm. The discussion which followed Prof. Larson's address was led by Dr. Roger G. Perkins, professor of hygiene at Western Reserve University, who described the successful use of Prof. Larson's toxin in Cleveland, and uttered a warning against allowing the public to believe that biological methods would ever be successful in 100 per cent. of cases. Dr. Peters described successful arrest of epidemics of scarlet fever in Cincinnati by the use of the same toxin, and other speakers also gave personal testimony to its efficacy in practice. In answer to inquiries about the possibility of obtaining the toxin, Prof. Larson said that he had sent out over 50,000 doses of scarlet fever toxin, and that the present demand was beyond the means of a teaching institution. He has therefore instructed one of the large commercial houses in his technique, and his material will soon be on the market.

THE MEDICAL USES OF RADIUM.

THE stock of radium salt entrusted by H.M. Government to the Medical Research Council is being used at 11 centres, distributed through the country, for the treatment of disease. Every year these centres furnish a report of their activities to the Radiology Committee, appointed jointly by the Council and the British Empire Cancer Campaign, which body has added to the stock of available radium, and on this committee falls the difficult duty of collating the reports—diverse as to manner as well as matter—into a readable account of progress made. This year, in No. 112 of the special report series,[1] which contains reports on cancer of the breast, uterus, mouth, nasopharynx and larynx, œsophagus, rectum, bladder, and prostate, no reference is made to the treatment of rodent ulcer or to non-malignant conditions. The reason given for these omissions is that suitable radiological treatment for the former

[1] H.M. Stationery Office, 1926, pp. 34, 1*s.* 6*d.*

and for many non-malignant diseases is now well known. The technique adopted by common consent at the centres in the treatment of menorrhagia is also considered to have reached a stage which carries it beyond urgent need of further research. The benefit conferred by radium on those suffering from the leukæmias is now known to be short-lived, the blood picture soon becoming abnormal again. The section of this report which is of most interest is that on cancer of the cervix, since a brief account of the technique used at each of the centres is supplied, and an analysis has been made of statistical data, collected from four of the centres, of patients treated since 1922. Of 214 cases, with few exceptions inoperable, 120 are dead and 36 have not been traced. At a period not less than a year after treatment 31 were alive but not free of disease, while 27 were apparently well. Of 20 borderline or operable cases the corresponding numbers were 4, 4, 6, and 6. From the accounts of technique it is obvious that there is still a considerable degree of variation in the dosage of radium used and in the manner of its application. The introduction of 50–100 mg. into the cervical canal for 22 to 24 hours is a measure common to all except St. Bartholomew's Hospital, where a study of the effects of much smaller quantities acting continuously for six days is being made. Growths which cannot adequately be reached by radium tubes in the cervical canal are treated in some centres by packing applicators round the tissues involved, while others insert needles into the growth, care being taken to avoid proximity to rectum or bladder. In spite of these differences there seems to be more hope of soon establishing a standard technique in cancer of the cervix than in most other regions. Once this has been agreed on, it will be less difficult to ascertain the scope of radiotherapy, and especially to decide whether it should be advocated as a substitute for excision of the growth in operable cases or only as an ancillary measure to prevent recurrence.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCI.—THE TREATMENT OF CHILBLAIN (ERYTHEMA PERNIO).*

II.—THE MANAGEMENT OF THE CASE.

FROM what was said in the preliminary considerations of the ætiology of chilblains and of those susceptible to them, it will be clear that their treatment must vary according to the type of patient with which one has to deal, and should, whenever possible, be preceded by a thorough physical examination. In particular it is necessary to search for any chronic infection which may be lowering the patient's resistance—for example, tuberculosis of lymphatic glands or other organs, persistent nasopharyngeal catarrh, nasal-sinus disease, septic tonsils, or oral sepsis. There are points about the general treatment of patients with a tendency to chilblains which are applicable to all cases. Unfortunately, however, among the majority these are seldom practicable for social and financial reasons.

Diet and Exercise.

With our modern knowledge of biochemistry and bacteriology—incomplete as it is—the rational rules of diet are so obvious as to be almost platitudinous. Briefly the indications in these patients are:

(1) To modify the diet according to the patient's mode of life; the more sedentary the latter the less should be the amount of carbohydrate taken.

(2) To ensure an adequate supply of fresh food containing mineral salts and vitamins; green vegetables and mixed salads, fruit, particularly apples, wholemeal or Swedish bread with plenty of butter, eggs, preferably raw, milk, cheese, cream, and a moderate quantity of freshly cooked meat and fish should form the basis of a normal diet. With regard to fruit, however, the decalcifying action of certain very acid fruits should be remembered.

(3) In patients with symptoms of excessive intestinal putrefaction the amount of meat and fish should, of course, be reduced to a minimum and the quantity of carbohydrate and fresh vegetables and fruit increased.

(4) Conversely in those with intestinal fermentation and excessive acid production, all soft starchy and concentrated sweet foods must be excluded. The great majority of these patients have been or are being wrongly fed, the common fault being an excess of carbohydrate and a lack of fresh dairy produce and uncooked vegetables and fruit.

It is clear that physical exercise, preferably out of doors, provides the best method of improving a sluggish peripheral circulation, but, of course, the amount taken must be regulated by the patient's physique, and the presence or absence of a chronic infection—tuberculous or otherwise—must be taken into account. Jacquet's biokinetic method of treating chilblains, if conscientiously carried out, is of value. The patient fixes the finger- or toe-joints by forcible muscular effort, and holds them extended in an elevated position for five minutes several times daily.

Sunlight.

Except in rare cases chilblains disappear spontaneously in summer, and are much less common in a cold dry atmosphere than in damp chilly weather. Apart from this, heliotherapy and, to a less extent, artificial light baths are of great value in the treatment of patients with acrocyanosis. I have, however, seen a patient with lupus erythematosus develop chilblains while under intensive treatment with carbon-arc light baths.

The beneficial action of ultra-violet light in these cases is probably complex. It undoubtedly affects the vasomotor system as well as other parts of the sympathetic nervous system—viz., that controlling the pigmentation of the skin, the fibres supplying the hair-bulbs, and those responsible for muscle-tone. Many patients state that after a course of heliotherapy or light baths they "feel the cold" far less. Apart from increasing vasomotor tone ultra-violet radiations act on the endocrine glands, particularly on the thyroid and parathyroids, but also on the ovaries and testes. As regards chilblains it is probable that the action of ultra-violet light on the sympathetic and certain of the endocrine glands is chiefly responsible for its beneficial effect, but its power of raising the calcium concentration in the blood may in some cases be an important factor, and in this connexion it is of interest that the experiments of Grant and Gates of the Rockefeller Institute (quoted by Howard Humphris [1]), appear to show that the parathyroids are more profoundly affected by ultra-violet radiation than the other endocrine glands.

Clothing.

Too little importance is unfortunately attached to the question of clothing by the medical profession, and it is a sad reflection that the emancipation of women from the unhygienic frills and furbelows of the Victorian age lies to the credit of the modern costumier and not to ours. It is high time that our more conservative tailors and hosiers condemned the Eton suit, the heavy tweeds, and winter underclothing to oblivion. Fortunately the system of compulsory games that obtains at preparatory and public schools ensures that boys wear a rational costume for, at any rate, part of their daily life. Needless to say, a patient subject to chilblains should be advised to keep the extremities warm with loose woollen gloves and stockings, but the rest of the clothing should be light and porous, and whenever possible vigorous out-

* An article on the Treatment of Chilblains—I. General Considerations—appeared in this series last week.

[1] Artificial Sunlight and its Therapeutic Uses, Oxford Med. Pub., 3rd edit., p. 71.

door exercise with the minimum of covering should be enjoined, so that the tonic effect of air and sunlight on the skin may be obtained.

Drugs.

The administration of drugs internally for the relief of the chilblain tendency is of far less importance than the prophylactic measures as regards diet, exercise, and sunlight, outlined above. At the same time their temporary use may be of the greatest value in order to correct any abnormal state that may exist in the individual patient under treatment. In the fat type I have found, as a rule, that thyroid gland, which should be pushed until the optimum dose is found, and iodine in large doses, bring about striking improvement if persisted with. The latter may be given as the French tincture (French Codex, 1908) dispensed in a drop-bottle and taken in milk, beginning with 5 drops twice daily and increasing up to as much as 60 drops in divided doses per diem. Symptoms of intolerance must be watched for, and when, as often happens, the patient develops a repugnance for the drug, it should be discontinued for a while. Iodicin, a calcium salt of iodo-ricinoleic acid, or some similar organic combination of iodine may be used as an alternative to the tincture. Colonic stasis is the rule in these patients and should be corrected by the temporary administration of saline or other aperients and liquid paraffin. If there is colonic spasm, belladonna is of course indicated.

It is as a rule in the thin, nervous, *chétif* patient that calcium salts are most likely to be of benefit, but their effect may well be tried in all cases. They are no doubt best given by injection, but for convenience's sake are usually taken orally. Afenil—a calcium chloride-urea compound—is much used on the Continent; it is supplied in 10 c.cm. ampoules for intravenous injection, and a course of from six to eight injections at intervals of a few days is advised. For intramuscular injection a solution of calcium chloride, or Crookes Collosol calcium may be employed. Orally calcium lactate in doses of 15–20 gr. thrice daily, preferably about an hour before meals, or the proprietary compound of calcium and sodium lactate known as kalzana are convenient and pleasant to take. There is still considerable scepticism as to the activity of parathyroid gland when given by the mouth, but evidence from independent sources has now accumulated to show that reliable preparations are on the market and that their oral administration does increase the concentration of ionisable calcium in the blood. Cod-liver oil is of unquestionable benefit, particularly in thin patients with a low resistance to infection. Brocq advises a combination of thyroid with pills containing quinine hydrochloride, ergot, and digitalis leaves.

Local Measures.

Local measures for the relief of chilblains are clearly of secondary importance, and it is unnecessary to enumerate the various applications that have been advised. Apart from the biokinetic method of Jacquet already referred to, probably the most efficacious local treatment is by means of galvanic reversals. The patient's hands and forearms are immersed in baths of warm water, through which is passed a galvanic current, the latter being periodically reversed by means of a converted metronome. A course of daily treatments of from 10 to 20 minutes is given over a period of two or three weeks at the beginning of the winter. Another method that often gives remarkable relief is the immersion of the affected parts in hydrogen peroxide 15 vols., diluted with an equal quantity of hot water, for ten minutes, followed by vigorous friction with a rubefacient such as methyl salicylate ointment or spirits of camphor. Ointments containing ichthyol, iodine (e.g., iodex), balsam of Peru or storax are also efficient. In severe cases by far the best preliminary treatment is to put the patient completely at rest in bed, mild antiseptic applications being made to any ulcerated surfaces.

EPSOM COLLEGE.

AN APPEAL TO PRACTITIONERS.

I ASK every medical practitioner to be so patriotic to his profession as at least to read this letter. Epsom College needs a new sanatorium and isolation block. The existing one is out of date in its accommodation and arrangements, is uneconomical in its working, and affords no facility for the isolation of infectious cases. This purpose, of such paramount importance in a public school, is at present effected by a wooden hut, which is licensed only for a few years more. The vacated sanatorium would, however, with a limited amount of internal adaptation provide excellent residential quarters for at least 40 more boys, and so enable the Council to house some of the numerous applicants whom they have to refuse annually.

Epsom College, as the offspring of the medical profession, should show a sanatorium that would be a model for all other schools to copy. Such an object should appeal to the pride as well as to the philanthropy of the profession, and some £25,000 is a sum that would enable us to gratify both. We cannot hope for many large donations from a profession in which few are rich, but no other profession has more ready access to rich laymen, who may desire to bestow some of their wealth on suitable objects of charity. Here is an object that combines an educational with a philanthropic purpose.

There are over 50,000 practitioners on the Medical Register. Ten shillings from each would provide this haven of rest for the reception of sick sons of generations of medical men, and perhaps for your own. But as experience has taught us that such a unanimous response is not to be looked for in our or indeed in any profession, we ask those who can to send larger donations to compensate for those who send nothing. Annual subscriptions do not even afford the balance required for maintenance, so that for all structural improvements we have to depend on legacies and extraordinary donations. Remember *qui facit per alium facit per se*, and great gratitude will be due to those who can supplement their own gifts by influencing donations from others.

The donor of £10,000 may give his own name, or the name of any person whom he or she desires to commemorate, to the main block of the sanatorium, and the donor of £5000 may do likewise to the isolation block. A large ward may be named for £3000, and a small ward or the casualty department for £1000, while £100 may determine the name of a single bed. Each medical school might well confer its name on a single bed.

This complete scheme should not be beyond the ready accomplishment of the profession with the help of some of those not rare persons who feel that they owe a debt of gratitude to some honoured medical attendant. We can do it, if we have the will to do it, but this condition is an essential prerequisite.

The *British Medical Journal* and THE LANCET of their goodness have promised to publish lists of all subscribers, both small and great, from time to time. I beg you to figure on these lists by sending what you can to the "Sanatorium Fund" to the Secretary at the Epsom College Office, 49, Bedford-square, W.C.1, or to the office of either of the above-named journals to the credit of the Fund.

RAYMOND CRAWFURD,
Chairman of the Council of Epsom College.

November, 1926.

PROBLEMS OF MENTAL DEFICIENCY.

CONFERENCE OF THE CENTRAL ASSOCIATION FOR MENTAL WELFARE, DEC. 2ND-3RD, 1926.

AT the morning session on Dec. 2nd the chair was taken by Sir LESLIE SCOTT, K.C., the President. We were just beginning, he said, to realise that there would always remain a number of defectives who would never enter institutions or who would only spend a few years in them. What was hoped for was effective control of those who were antisocial and unbalanced, leaving for community care those who in the right environment could live a fairly happy and useful life. The community benefited directly by having trained, controlled defectives living in it. He urged the practical development of the handicraft centres, and pointed out that development depended on the right people being in charge. The borderland case was an even more difficult problem; mental defectives formed but a small percentage of that great army of failures of civilisation for whom it was our duty to provide just that additional help which would enable them to help the world. Unlike the defectives, the borderland cases might in the end be made useful and helpful members of society, if proper treatment were begun early and continued steadfastly. Expenditure on this aim would be a real form of national economy.

Miss RUTH DARWIN (Board of Control) then opened a discussion on the

Proper Care of Defectives Outside Institutions.

She pointed out that the number of defectives in our present population based on the estimate of the Royal Commission was 174,000, and that about half of them were in urgent need of care. The total number under supervision of some kind was 53,664, of which 20,297 were in institutions and homes. It was clearly impossible, even if desirable, to segregate the whole defective population. The care required for those who must remain outside institutions was partly in the interest of the individual and partly in that of the community. The speaker had no doubt that most defectives were happier under care; the small group who chafed against control and enjoyed brief pleasures in liberty usually consisted of those whose antisocial and vicious tendencies made them so unfit to manage their own lives that their liberty was sooner or later taken from them by the criminal law. Whether the right of the community to safeguard itself at the expense of the individual should be extended to the enforced segregation of defectives to prevent the procreation of children was a question of fundamental importance which had never been fairly faced. Quite apart from heredity, the chance of the children of defective parents of becoming independent, self-supporting citizens was small. Several statistical inquiries had made it certain that the less skilled sections of the nation were multiplying more quickly than the skilled, and that the full effects on the race were only now beginning to be felt. It seemed a reasonable assumption that a large proportion of the borderland cases of mental defect were to be found in this rapidly reproducing stratum of society, which was therefore a very grave matter. The most immediate and obvious measure to prevent a deterioration in the quality of the race, due to the elimination of natural selection from modern life, was to prevent procreation by persons whose mental defect made them unfit to become parents. There could not be two opinions as to the desirability of relieving future generations as far as possible from the burden of maintaining a group of persons incapable of leading a full life or making any return to society.

Provisions under the Mental Deficiency Act.

The number of mental defectives now ascertained amounted to 55,480, and it seemed justifiable to conclude that in certain areas the existence of large numbers was still unknown to the responsible authority. The non-institutional methods contemplated by the Act were doomed to failure unless their limitations were recognised. Careful discrimination was needed as to the type of case for whom such care would afford sufficient protection. The only safe and humane treatment for defectives with antisocial and immoral tendencies was institutional care. Even the steady-going harmless individual was a danger to himself and others unless favourable surroundings could be ensured. Regular visitation and reports were necessary and must be provided by visitors experienced enough to recognise early symptoms of trouble. Occupation centres provided a most satisfactory means of keeping in close touch with defectives living under guardianship. Lack of recognition of these principles and shortcomings in the working of the Act had resulted in the marriage of 195 adults, the adoption of immoral relations or perverted sexual habits by 252 more, and the birth of 275 children. These figures were serious, and it must be remembered that they related only to cases under statutory supervision. As long as the shortage of accommodation continued, defectives unfitted for free life must be left in the community. Another difficulty was that the officers in some areas were primarily appointed in another capacity and had not sufficient time for this work.

The Marriage of Defectives.

A third difficulty was that there is nothing in the law to make the marriage of a defective illegal or invalid. The speaker suggested that marriage and procreation might be limited under the present Act in the following ways. Full use should be made of the powers under Section II. (2) of the Act, and all cases notified should be provided with a home in a colony or carefully-considered guardianship. Better and more constant supervision by trained visitors should be sought, and lack of parental control leading to sexual irregularities should be regarded as "neglect" bringing the individual under care. Where there was risk of marriage, every effort should be made to get the parents to consent to institutional care.

Sterilisation.

Sterilisation, as a measure supplementary to the Act, deserved the fullest consideration. Cases would have to be selected with a view to each individual's mentality and temperament and the conditions to which he would return, and the consent of the parent or guardian would be necessary. If the danger of procreation were eliminated, a larger number of cases might safely be recommended for release from institutions. There should be great elasticity in the treatment of defectives. The only panacea for mental deficiency lay in a higher standard of human conduct and ideals; in the meantime there was urgent need for the provision of new colonies; better ascertainment, supervision, and training; investigation and experiment into new methods for fuller training of workers; more careful selection of guardians, and coöperation amongst all engaged in practical or scientific work connected with mental welfare.

Dr. A. F. TREDGOLD said that the policy of sterilisation was absolutely wrong in theory; the number of defectives who were the offspring of people who might have been sterilised was infinitesimal. The whole of the available evidence indicated that mental defect was not inherited according to Mendelian law. In practice sterilisation would probably lead to increased sexual irregularity, which meant increased venereal disease. To draw the line would be exceedingly difficult, and the measure would undoubtedly be used as a pretext for delaying the necessary increase in institutional accommodation and for releasing cases who ought to be in homes. The matter had been most carefully considered by people with absolutely open minds, and this was the conclusion to which they had come.

Mrs. HUME PINSENT (Board of Control) said that there could be no two opinions as to the importance of preventing the procreation of mental defectives;

the condition of their children was enough to make the most cynical ashamed of our civilisation; they were the despair of all social workers, since the mother was the irreformable source of all their suffering, disease, and crime. Making marriage void would not prevent the birth of children, and no amount of supervision outside institutions could prevent it either. The subject of sterilisation with consent was one on which much further thought should be expended; it might free some who would otherwise remain all their lives in institutions, and would be a valuable social experiment.

Special Schools.

Any curtailment of expenditure on education meant knocking the bottom out of the Mental Deficiency Act. Notification was the recognised means of linking up the educational and mental health services and the only means of securing proper care for defectives, but it was not properly carried out, as literally hundreds were never ascertained and left school at 14. The local authorities could not deal with them until they were 16, and in this gap many were lost sight of and never heard of again until they appeared in prisons or Poor-law institutions. By that time irrecoverable opportunities had been lost, and there was nothing for them but segregation.

Mr. J. SANDEMAN ALLEN (Chairman, West Lancashire Association for Mental Welfare), in a paper taken as read, said that the Act of 1913 placed upon the local authorities the responsibility of safeguarding the community and the defective by an extension of the existing institutional care and by the introduction of the entirely new method of continuous and lifelong supervision. Only a very few children were so developed by a special school training as to be fit to join normal children; for the majority their costly education was wasted unless they stayed at the school until 16 years of age and received care and supervision throughout and for the following few years. Leaving them to the care of their parents or of an after-care committee was not satisfactory. The responsibility of recommending mental defectives for occupation called for continuous and increasing study.

Meaning and Effectiveness of Supervision.

No definition of supervision was given in the Act, and it was left to the interpretation and imagination of local authorities. The greatest problem to be faced by any voluntary association was how to make supervision in any degree effective. It must take into account the family environment and standard, the degree of defect, and the age of the defective. For a young and deeply defective child in a poor home the aim should be to encourage the mother to train the child in regular habits, decency, and cleanliness, to secure medical treatment for minor ailments and some holiday where possible. For an excluded imbecile, training in a centre should be added to the desiderata. Cases notified for supervision on leaving school, and adults, should be urged to continue some form of manual work in an employment centre, advised as to suitable recreation, and their occupations, if any, investigated as to suitability. The most difficult cases were often those on licence from an institution with a view to discharge. In a careless home they did not get a fair chance. Hostels, as a kind of half-way house between the institution and freedom, and for the ex-special child with an unsuitable home, would be an expenditure that would very soon show itself as an economy. A most valuable aspect of the work of a voluntary association was coöperation with other such bodies. Nevertheless, the hold must be a very loose one, and sometimes totally inadequate, and the defective could only be allowed to go on until he got in trouble with the police or the parental neglect became gross enough for action by the local authority. Occupation centres had been accepted almost universally as an adjunct to supervision, but the older patients could not be retained indefinitely as the younger ones came in. The West Lancashire Association hoped to open a combined club and handwork class for older defectives.

Borderland Cases.

The most difficult to deal with and possibly the most dangerous of all cases was the hydra-headed class known as "borderland," which ran the whole gamut of social welfare effort and exhausted everyone's patience and resources before being recognised as uncertifiable mental disorder. In their ranks were the potential criminal and prostitute, the incurably vagrant, the young hysteric, the potential suicide and murderer, the neurotic invalid, the emotionally unstable, victims of their temperament and the prey of the unscrupulous. Another similar class was the subnormal criminal who might, perhaps, be sufficiently supervised to prevent a life of crime, but so far no one seemed to have solved the problem. Colony life, at present impracticable, seemed to offer the only hope.

Procreation.

It was a strange anomaly that, while it was illegal for a defective under certificate to marry if in an institution or under guardianship, he became free to do so if discharged. In mental deficiency there was no "cure," and discharge only meant sufficient improvement to warrant the hope of earning a living or some change in the home conditions. It should be made illegal for certifiable defectives to marry. Sterilisation would probably increase the evils of promiscuity and prostitution and still leave the problem of the normal person who is a "carrier" of mental defect.

Dr. RALPH CROWLEY (Board of Education) said that one-fifth of the children in the special schools had an intelligence quotient of over 70 and another one-fifth below 50; roughly one-third of them required custodial care. An inquiry into the after-history of a number of boys showed that one-seventh of them only could be described as unemployable, and that two-thirds were in regular work. They were less restless than normal children, and willing to go on doing donkey-work. It was not true that the special schools were full of children who would be a danger to the State. He pointed out that present methods gave a series of "transverse sections" of the lives of these people, and appealed for long-continued watching, which would give a reliable "longitudinal section."

Dr. H. BURPITT (Newport) pointed out that the appointment of a special officer for mental deficiency work was not always the best way of enlisting the sympathy of the parents, who were apt to get tired of a series of visitors.

Councillor Miss EMILY FORTEY (Leicester) said that parents were apt to evade special schools by sending their children to private establishments, and suggested that this might be stopped if certification under the Mental Deficiency Act could be dispensed with for special schools.

Mr. W. H. FLETCHER (London Teachers' Association) said it was most disquieting to learn that the number of children in special schools had steadily decreased during the last five years, since the numbers of defectives had certainly not decreased. He pleaded with doctors and head teachers not to be loth to send children forward so that they came under statutory examination. Many boys stayed in general schools until they were 13½, and then got certified, but by that time they could never receive the special groundwork and training they needed.

General Discussion.

Dr. R. HUGHES said that in Stoke-on-Trent the gap between 14 and 16 had been bridged by an unofficial notification from one medical officer to the other.

Mrs. EMMETT (Bradford) bewailed the inadequacy of supervision and the helplessness of workers who could only pay periodical visits. Any mental defective without training was likely to become helpless, dirty, and uncontrolled. Occupation centres

alone held out hope, and the patients should be given some small weekly wage and those with unsuitable homes boarded out. For every penny we said we could not afford to-day, the future generation would have to pay a pound.

Miss DARNELL (London Association) spoke of the early difficulties of statutory supervision in her area and the impossibility of getting the trust and coöperation of the parents unless fully trained and sympathetic workers were ready to give individual treatment to each case. Both she and Alderman KATHLEEN CHAMBERS (Bradford) emphasised the great value of and need for occupation centres.

On Thursday afternoon the Right Hon. H. P. MACMILLAN, K.C., took the chair, and a discussion on

Borderland Cases

was opened by Lieut.-Colonel E. GOODALL (Superintendent, Cardiff City Mental Hospital). He said that mental and nervous disorders caused more widespread havoc and misery in the home than any others, but no provision was made for the early institutional treatment of these maladies, and they did not often benefit by the munificence of philanthropists. He quoted the evidence given by Sir F. Mott and himself before the Royal Commission on this subject, and emphasised the need for linking up psychiatry with general medicine (vide THE LANCET, Sept. 11th, 1920). The practical teaching of psychiatry to medical students and nurses in this country was absurdly inadequate. He quoted the Boston Psychopathic Hospital as an ideal psychiatric clinic.

Dr. W. R. K. WATSON (Senior Medical Officer, H.M. Prison, Brixton) said that he thought the subnormal population of this island might safely be calculated as one million. Experiments on prisoners showed that their intelligence did not fall below the general average, although the delinquent group contained a slightly higher percentage of subnormals than the non-delinquent population. Not more than 5 per cent. of subnormals were delinquent; most of them were amiable and harmless, and indeed formed a very useful part of the people, willing to undertake humble unskilled labour. He doubted whether the proportion of subnormals was higher now than it had always been, and thought that in any given family the tendency still was for mental defect to die out. The majority of subnormal delinquents showed not so much intellectual defect as emotional instability, and many of them were unfit for prison discipline. Such cases were always regarded as medical, and were specially treated. While our prisons might not be the best conceivable places for borderline cases, they were the best at present available. The most promising plan for improvement would be to set aside certain prisons for the various kinds of borderland delinquents; a start in this direction had already been made. It was very rare for these people to show shame at the idea of prison; their infirmity automatically mitigated their punishment.

In the subsequent discussion Dr. T. A. ROSS said that the problem would never be satisfactorily solved until every hospital had its mental clinic, and Dr. HELEN BOYLE ridiculed the idea that there was not enough money for the required measures: it was apathy, slackness, and want of understanding that blocked reform. We needed well-informed social workers, good vocational guidance, clinics with beds, and a wider outlook in social service.

Dr. H. CRICHTON-MILLER said that it was time that some central administrative department undertook the responsibility of providing a suitably mitigated environment for the neurotic and the criminal, who suffered from the common trouble of mal-adjustment.

Dr. LETITIA FAIRFIELD said that the statistics published by the Board of Education were quite unreliable, and nobody had any idea how many backward and defective children there were in the country. It was most important to get hold of the mal-adapted child early in its life.

On Friday, Dec. 3rd, the morning session was occupied with a discussion on the Training of Teachers for Special Schools, under the chairmanship of Dr. H. B. BRACKENBURY.

At the afternoon session Sir ARCHIBALD BODKIN took the chair, and opened a discussion on Encephalitis Lethargica and its After-effects.

(To be concluded.)

MEDICINE AND THE LAW.

The Case of Miss Marmion.

IN the note on this case of alleged manslaughter published last week, it was stated that after the briefest of intervals the jury found the two accused doctors "not guilty," their commitment on the coroner's warrants being, as usual, ignored. It should be added that both the doctors had visited the local police-station immediately after Miss Marmion's death to report the circumstances, and both gave categorical evidence in their own defence. They were asked in cross-examination why they had not given to the coroner the full explanation which they gave at the Assizes, and this point was, naturally, pressed, for the earlier a defence is disclosed, the better impression of bona fides is given. But it must be remembered that a coroner's inquest is a peculiar tribunal. It is a roving inquiry, with no parties to the record, and indeed with no record at all until the coroner's jury has given its verdict. No detailed charge of crime is investigated; there is no definitely accused person, and there are no strict rights of calling witnesses on behalf of any person whose conduct may be reflected upon. When, as in this case, pathological evidence is given at the inquest on behalf of the police, persons who are likely to be accused of crime are reasonably advised to defer defence until they know exactly where they stand. It was mentioned last week that Mr. Justice Branson informed the jury that he entirely agreed with their verdict of acquittal. Legal purists deprecate such expressions by judges on issues of fact which are outside the judicial province; a jury does not require a judge's approval or disapproval of its verdict, and, if approval is to be expressed generally, a judge's silence may carry the imputation of disapproval. But the judicial confirmation in the present case will be gratifying to the acquitted doctors and to the London and Counties Medical Protection Society, by whom their defence was undertaken.

Hospital Refuses Attempted Suicide.

At an inquest held at New Mills, Derbyshire, on Nov. 23rd on a married woman aged 33, who died after drinking lysol, it was stated that she was ordered to be taken to Stockport Infirmary on Sunday, Nov. 21st, the day after she drank the disinfectant. On arrival at the hospital the woman was asked if she took the lysol herself. She replied that she did. The surgeon stated that suicides were not taken into the hospital for treatment and provided a note for the woman's admission to the Shawheath Union Hospital at Stockport. On arrival there the husband discovered that Shawheath was a Poor-law hospital, and declined to allow his wife to be taken in; she was brought home and died a few hours later. The coroner had asked the police to let the authorities at Stockport know that the woman had since died, and to ask them if they would like to attend the inquest. A letter was received from the resident surgeon, stating that they are not allowed to take suicide cases into the hospital for treatment, because the police do not find it possible to allocate to them people who are not responsible for their after actions. Provision had been made for such cases at Shawheath and the hospital authorities had been requested to transfer any cases to that hospital for treatment. This happens in every case, and is one of the regulations of the hospital. The coroner returned a verdict that the woman died from lysol poisoning taken during depression caused by ill-health.

Medical Witnesses and Long Journeys.

At Romford on Monday last, Judge Crawford protested against the time of two medical men being taken up unnecessarily, long journeys being involved, in an action which might easily have been heard in the district in which the accident happened. In the case before the court—a motor collision—the accident occurred near Uckfield, Sussex, and plaintiff, who lives at Eltham, brought the action at Romford as defendant lives within the jurisdiction of that court. To prove his case—which, incidentally, he lost—he called Dr. Cyril Williams, of Uckfield, who is attached to the Cottage Hospital, and Dr. John Higginton, of Eltham. Dr. Williams, before giving evidence, said he would like to know whether he was entitled to reasonable remuneration for his services. In order that he might reach the court at the proper time it had been necessary for him to travel to London on Sunday night, and engage another doctor to carry out his duties during his absence. For this he had just been paid one guinea. The judge said that such a payment was ridiculous. The doctor was entitled to reasonable expenses for all the trouble and inconvenience he had been put to. Counsel for plaintiff said they did not know Dr. Williams had had to travel to London the previous night. He had consulted his clients in the matter. Judge Crawford: "Consulting your clients does not give Dr. Williams much satisfaction. He should be paid proper expenses. I have no power, unfortunately, to order it, but I hope it will be done." Later the judge again referred to the subject. One doctor, he said, had been called from Sussex and another from Eltham, to the great inconvenience of both. There was no reason whatever why the case could not have been tried in a court where the hearing would not have necessitated such long and unnecessary journeys.

COLLOIDAL LEAD IN MALIGNANT DISEASE.

DEMONSTRATION BY THE LIVERPOOL MEDICAL RESEARCH ORGANISATION.

(FROM OUR LIVERPOOL CORRESPONDENT.)

A SMALL but representative and distinguished gathering were present on Nov. 30th, when, for the fourth year in succession, a general demonstration was given of the methods and results of the treatment of malignant disease by the intravenous administration of colloidal lead. Surgeons attended from London, provincial centres, and several foreign schools, while the chemical and laboratory side of the work was submitted to investigation by men eminent in these branches.

The day began at 9 A.M. with a short address by the Director, Prof. W. BLAIR BELL, on the aims and methods of the organisation. This was followed by a demonstration by Prof. ERNEST GLYNN. It was usually very difficult, he said, to decide whether histological changes found in human cancer after lead were due to the treatment, because regression, at least in certain areas, was characteristic of malignancy. In the following case, however, the evidence that lead had produced extraordinary histological changes was conclusive, though associated sepsis might have contributed in some obscure way.

H. A., male, aged 46, had a spheroidal-celled cancer of the breast of 17 months duration excised. Lead was administered immediately afterwards. The total received in 18 days was 0·175 g., the last dose was 0·075 g. 11 days before death. He died from empyema. There were a few metastases in the liver, suprarenals, lungs. Five of these, examined microscopically, showed an extraordinary regression of the epithelial cells; they resembled those of a badly-preserved sarcoma, though the post-mortem was only 30 hours after death. There was practically no "healthy" cancer. The same changes were present in an infected fibrosed lymphatic gland, though less marked, for some of the epithelial cells appeared healthy, even mitoses being present.

The lesser degree of regression in the relatively avascular and fibrosed lymphatic gland indicated, said Prof. Glynn, that the action of lead chiefly depended upon a well-developed and unobstructed blood-supply and perhaps lymph-supply. It was histological evidence of an inherent difficulty in treating cancer by lead or any other drug or by serum.

Prof. W. J. DILLING then spoke briefly on the work carried on in his department to test the toxicity of the various lead suspensions used. All were thoroughly tested on animals. It was found that those prepared by Prof. Lewis had practically no toxic effects upon pulse, respiration, cardiac action, or blood pressure, although even small variations in the technique of manufacture were sometimes followed by serious results as regards toxicity. A series of tracings were shown making abundantly clear the points referred to.

Laboratory Demonstration.

In the Muspratt Laboratory of Physical and Electro-Chemistry Prof. W. C. M. LEWIS, F.R.S., in the course of a brief account of the general programme of work that was being carried out in physical and bio-chemistry, discussed in particular the problem of permeability of tissues from the standpoint of the work of Clowes, and the phosphatide and cholesterol contents of tissues. Emulsification experiments had shown that phosphatides favoured permeability, whilst cholesterol lessened permeability. On this basis, analyses of normal and malignant tissues led to the conclusion that malignant tissues had a raised permeability. Reference was also made to the problem of determining hydrogen-ion concentration.

Dr. M. JOWETT reviewed briefly the subject of glycolysis, and discussed preliminary results that had been obtained on the glycolytic behaviour of rabbit chorion and on the effect of lead on glycolysis.

Dr. H. MILLET described the methods in use of making lead suspensions, and referred to methods of stabilisation.

Dr. J. BROOKS gave an account of work bearing on the fate of the lead suspension in blood, which showed that conversion into lead phosphate ultimately took place.

Demonstrations were then given of the preparation and testing of the lead suspension, as prepared in the Muspratt Laboratory, and of its ultra-filtration and cataphoretic behaviour, together with the methods used in studying glycolysis.

Cases and Specimens.

The party was escorted at 11.15 to the new gynæcological theatres of the Royal Infirmary, where a number of patients were shown. The specimens, where such had been removed, with their microscopic appearances, had previously been exhibited in the obstetric department of the University. Some of these were exceedingly striking, although not necessarily to be taken as examples of cure of malignant disease. For instance, there was a patient with an inoperable carcinoma of the rectum who had had a colostomy done for the disease in September, 1925. Examination by a distinguished London surgeon failed to detect anything abnormal. A point of further interest in this case was that although six months pregnant at the time when lead treatment was commenced, she had gone to full term and been delivered naturally of a healthy child. There was also seen a patient whose breast had been removed for cancer in 1921 and who had had a recurrence, so that in January of this year the condition was regarded as quite inoperable, there being a hard, fixed mass in the pectoral region and some œdema of the arm. She has now got no mass, although the region is slightly tender, and the arm is sensibly softer.

The visitors lunched with the staff at the Exchange Hotel and then adjourned to the Northern Hospital, where Dr. LOUIS CUNNINGHAM, the assistant director of the unit, showed a further series of cases. He then demonstrated and described the various points in the administration of the drug, speaking of its toxic effects, the dosage, and the precautions to be observed. The amount aimed at is 0·6 g. of lead given over

varying periods, the first course being often three doses of 15 or even 20 c.cm. of the 0·5 per cent. solution twice a week. The most careful observation of kidney efficiency and the blood changes is of fundamental importance. Patients are encouraged to return at intervals for further isolated doses, as, of course, the ultimate fate of the cancerous deposits in the body is still unknown.

A large number of patients was then shown at Prof. Blair Bell's nursing home, a few of whom may be briefly mentioned.

1. Malignant teratoma of testes, removed in Australia, secondary nodules in tibia and astragalus. Treatment by lead, followed by operation (16/4/25), foci lightly shelled out. No further symptoms. (0·825 g. of lead.)

2. Mixed cell sarcoma scapula (0·2 g. lead + X rays). Disappearance of growth and glands (3/3/24). No trouble since.

3. Carcinoma in lactating breast. No operation. 0·29 g. lead given 20/10/20. Now perfectly well and breast is functioning.

4. Carcinoma mammæ; inoperable on account of local fixation, January, 1926; full course of lead associated with X rays; now greatly improved and considered operable; microscope = spheroidal cell cancer.

5. Sarcoma small intestine confirmed by section; operation February, 1923, short-circuiting, growth inoperable; 0·45 g. lead: now in good condition.

6. Carcinoma uterus and vagina: uterus removed November, 1924, nodules in vagina left behind, but piece removed for section; nodules in vagina now all gone; 0·69 g. lead.

7. Carcinoma liver and omentum, confirmed by section; 0·28 g. lead, 19/7/23. Now in good health.

The following points were stressed by Prof. Blair Bell. Although many of the cases had received no treatment but lead, he believed that the right course to take at present was radical operation first, where possible, and then injection of lead within a few days. A large number of cases were first seen when their condition was already so desperate as to give no method a fair trial; even some of these had been restored to health. He had had to refuse to treat cases sent from elsewhere without microscopic evidence of malignancy unless he was able to get permission to remove a piece for section himself. The lead preparation, known as "chcriotrope," had, said Prof. Blair Bell, been withdrawn owing to the severe symptoms produced. Arrangements had been made, however, for supplying those centres where treatment was already being carried on. Certain centres had coöperated by sending workers to study the treatment in Liverpool, and one of these was able to report 8 cases out of 49 with disease apparently arrested or very greatly improved. It would be remembered that much the same percentage of success was claimed out of the first 250 cases treated. The total number of cases treated is now about 600.

Impressions of a Visitor.

The impressions left by the day's programme amount to this. A large amount of care and energy is being expended by the Research Association on the study of the effect of lead on the tissues, normal and abnormal, from the pathological, chemical, and toxicological points of view. This work is of a high order and likely to be of permanent value. The Liverpool workers recognise that the therapeutic side of the investigation is still in the experimental stage, and they are making every effort to check varying factors and to establish observed facts. Every facility was offered to the visitors for seeing the scientific activities of the organisation; they were free to handle the specimens and to examine and cross-question the patients. If some of the cases are viewed in an optimistic light, it should be borne in mind that such an outlook is essential if work of this kind is to go on at all; it is for others to supply the keen scrutiny of scepticism. The 49 cases submitted by Prof. Blair Bell form a very remarkable series, and although, taken individually, one might hesitate to pass judgment, taken in the aggregate it is clear that a step forward has been made towards the solution of the mystery of malignant disease, and other workers will have to take into account the results of the treatment with colloidal lead.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Back-strain as a Cause of Incapacity.

To judge from the discussion of Mr. W. A. Cochrane's admirable paper at the Edinburgh Medico-Chirurgical Society last week, the number of true persons who feign back-strain is extremely small; Mr. Cochrane himself could only remember one from his experience in the out-patient department of the Edinburgh Royal Infirmary. People who bring their complaints up to hospital are likely, of course, to be those whose pain is most severe, but Mr. Cochrane made it clear that correct diagnosis must take account of many elements which are not always emphasised. One contributor to the discussion said that during the coal strike he had observed a distinct falling-off in the number of cases of back-strain referred to him, which supports the opinion that the amount of malingering associated with the condition has been somewhat exaggerated. It was agreed that only active treatment on radical lines in the early stages would prevent much genuine disablement later; only too often the treatment of the first stage enables the patient to return to work, but leaves him a ready prey to subsequent disablement on slight strain. This is a very important point, and it is hoped that Mr. Cochrane's views and experience will be more fully discussed. The complicated factors leading to back-strain are now getting to the stage of really scientific analysis.

The Dr. Elsie Inglis Memorial.

It seems only yesterday that I last spoke with Elsie Inglis in Queensferry-street. I see the gleam of triumph in her eye as she told me how at last the Scottish Women's Hospitals were to be accepted, and how she had satisfied "the authorities" down even to the bed socks! Her work in Edinburgh, her heroic adventure in Serbia, her death as she landed from her great crusade, make one of the great stories of the world. It will inspire the future as her vivid presence inspired the past.

When the Scottish Women's Hospitals had done their work the remnant of the fund went to help in building the Dr. Elsie Inglis Memorial Hospital on a beautiful site commanding a view of King's Park, behind Holyrood. The other day this hospital, which is working under full pressure, was visited by a party of Women Citizens, who were charmed with everything about it—building, locality, and outlook—but were given a hint that funds are, or may be, a difficulty and that the number of beds may have to be reduced instead of increased. If this be so, it must be remedied. The hospital's work is in direct continuation of what Dr. Inglis did in Edinburgh from long before the war, and it is a worthy symbol of her adventure. Such a monument cannot be dishonoured and when the day comes to appeal for money the story of this woman, stirring once more the heart of her country, will triumph over every obstacle as she did herself.

A New Hospital for Falkirk.

Falkirk, the centre of the "light castings," has more than recovered from the industrial depression from which it suffered during the war, and a new hospital has been needed for some time. The present hospital has only 74 beds, and there is a waiting list of 400. Not long ago the Duke and Duchess of Montrose joined in the ceremony of cutting the first sod; the families which they represent—Hamilton and Graham—have been bound up with the history of Falkirk for hundreds of years. The new hospital will be built on a site of 12 acres; but, as this is not all available yet, the immediate objective is the provision of 130 beds, later increasing to 250. The institution will be fully equipped as a modern general hospital, but the scheme has one feature of unusual interest. Its promoters are negotiating with the burghs of Falkirk, Grangemouth, and Denny, and with the Eastern

District of Stirlingshire for the provision of a maternity hospital to be run as part of the new organisation, and this is an excellent example of the steadily growing coöperation between voluntary and official medical services. Such coöperation is manifestly in the interest of both. It secures to the hospital the advantage of definite ad hoc income, and to the local health authorities the advantage of a hospital adequate in size and equipment. There is a growing belief that the medical needs of the immediate future will best be served by larger units than the older cottage hospitals, and improved transport makes the use of these larger units possible.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

Thyroid Tumours in Bone.

AMONGST papers read at the Clinical Congress of the American College of Surgeons in Montreal was one by Dr. R. Alessandri, of Rome, entitled Thyroid and Parathyroid Bone Tumours without Primary Lesion of the Thyroid Gland. After alluding to the frequent metastasis of malignant thyroid growths of the skeleton, he pointed out that cases had been reported of secondary growth in bones where the lesion of the thyroid gland itself was not to be considered either clinically or anatomically as true thyroid neoplasm, but had all the characteristics of simple colloid or hyperplastic goitre. He believed that there were benign goitres which produced metastasis, although many authors had denied their existence, asserting that the presence of metastasis was a sure proof of malignancy. Most cases were undoubtedly of this type, but he thought that the question was not solved definitely; there were, indeed, cases in which no change in the thyroid was present. He described two cases in which he had operated on thyroid tumours of bone (of which illustrations were shown) without being able to discover any abnormality of the thyroid gland. Neither before the appearance of the skeletal growth, nor during its development, nor after the operation, had the thyroid exhibited the slightest change or enlargement. Neither in those regions of the neck, nor of the tongue, nor where aberrant glands could be found was there anything suspicious which could represent the primary site of a tumour whence the metastasis might have come. It was not, he thought, possible to suppose the presence of a primary neoplasm; even if small it should have been present before the localisation in bone, and ought to have revealed itself before the end of the considerable time mentioned in the reports. Dr. Alessandri, therefore, thought that it must be admitted that bone tumours of the thyroid or parathyroid type could be found without any primary lesion of the normal thyroid gland or of an accessory gland.

Rabies in New York City.

The Health Commissioner of New York City, Dr. Harris, has been drawing the attention of doctors and veterinary surgeons to the question of establishing stations at which dogs may be inoculated against rabies. He is going to propose a regulation to the Board of Health requiring owners of dogs to have them vaccinated against rabies as a condition of receiving a licence, and he has issued statistics showing that in the first six months of this year 200 cases of true rabies were found in an examination of 395 dogs. During a similar period in 1925, 25 cases were found among 152 dogs. The records compiled by the Department of Health from reports made by policemen and hospitals show that during the first six months of this year 7030 persons were bitten as compared with 4077 in the corresponding period of last year. Dr. Harris is anxious to impress on the medical profession the importance of specific treatment for persons bitten by rabid or suspected animals. The immediate reason for his campaign is the recent death from rabies of a boy in the outskirts of New York, but, as a matter of fact, this was an exceptional event. Although rabies in dogs is at present widespread, and large numbers of people are bitten every year, this is the first case of human rabies recorded in the city for more than three years.

Medical Examination of Students at Columbia.

Dr. William H. McCastline, medical officer of Columbia University, advocates annual medical examination of all students, and insists that medical examination should be made carefully and scientifically or not at all. Much harm is being done, he thinks, by careless routine examination, and the present perfunctory investigation is practically worthless. So as to carry out an adequate scheme, he suggests that money be raised to pay the staff of trained and experienced medical men essential to make the examinations properly, and he proposes that a medical service building, with suitable space and equipment, should be put up by the University.

The Hospitals of the United States.

In 1900 there were 2419 hospitals in the United States. In 1925 the total was 7340, with a combined capacity of 814,000 beds, requiring almost a million medical men, nurses, and employees to care for the 12 million patients treated. Having about one-nineteenth of the population of the United States, New York City possesses almost one-twelfth of the country's hospital beds; 134 hospitals are maintained, besides proprietary institutions and hospitals for the care of the mentally diseased. This public service represents an investment of about £40,000,000 in land, buildings, and equipment, and is worked at a cost of more than £8,000,000 a year. About one-third of the investment represents municipal institutions, the other two-thirds being derived from private philanthropy.

Medicinal Alcohol.

In order to prevent the diversion of medicinal whisky from its proper purposes, and in order to replenish and maintain the supplies available for prescription—this requires the distillation of 3 million gallons every year—the Treasury Department of the United States Government has proposed the creation by Congress of a private corporation which shall be a "beneficent monopoly," and shall have authority to buy and own all the medicinal spirits in the country. This corporation, if created, will be the sole source of supply of medicinal spirits from the time of its creation. It will provide for manufacture, under Government regulation, and for distribution of the liquor direct, by American railways express, to retail druggists. At present the medical man is allowed by law to prescribe yearly a certain amount of alcohol for medicinal purposes. It is argued that existing supplies of whisky have been reduced to enough for about five more years, and as whisky must mature for at least four years before being fit for medicinal use, its manufacture for replenishment ought now to be undertaken by the Government. Equally important, say the advocates of Government control, is the fact that existing laws make it impossible for the distribution of liquor to be so controlled that it cannot be used for ordinary drinking. When the Prohibition law forbade its manufacture and sale, some 60 millions of gallons of beverage whisky were left in the hands of private owners, who were authorised to sell it to wholesale and retail druggists for medicinal purposes. It is claimed that the proposed new measure would lead to a very large saving in the administration of the Prohibition law, would ensure the supply of pure whisky for the patient on medical men's prescription, and reduce the cost to the purchaser. It would also abolish many of the abuses inherent in the existing system. Whisky is practically the only form of alcohol prescribed by doctors in this country.

New York Academy of Medicine.

On Nov. 17th a dinner was held in New York to celebrate the completion of the new building of the New York Academy of Medicine in 103rd Street and

Fifth Avenue. About a thousand medical men were present. The opening of the building marks the end of years of striving to find a suitable site for the Academy's home. The main difficulty has been to house the library, which contains 140,000 books, and is said to be the third largest medical library in the world. In the building just opened the books are contained in a separate building, four and a half stories in height, comprising nine floors of stack space with ample room for additions. This has two reading rooms, to seat 180 persons, and is open to all medical students and to medical men who are not members of the Academy. The periodical library alone contains 100,000 pamphlets and 1500 current medical and scientific journals. In the remaining building there is an auditorium with room for 700 people, and offices, lecture halls, and headquarters of medical societies.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH

THE following table gives some of the statistics for 1925 of the City of Manchester and four county boroughs. Dr. A. E. Brindley complains of unnecessary smoke in Derby, and that too little attention is given to its abatement, in view of the high death-rate from chest trouble. If, however, the Lancashire group of towns had had the same respiratory death-rate as Derby there would have been a saving of 1616 lives.

Name of town.	Estimated mid-year population (R.-G.).	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.	
			All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Heart disease.	Infant mortality.	Maternal mort. from childbirth.
Manchester .	758,235	18·6	14·4	1·56	1·39	3·5	1·5	96	3·2
Salford . ..	244,700	18·8	13·9	1·60	1·20	3·6	1·0	105	3·7
Bolton	180,400	16·3	13·6	1·02	1·33	3·1	1·7	87	4·7
Derby	134,400	18·9	11·9	1·00	1·26	2·2	1·6	74	2·4
St. Helens ..	109,600	23·9	12·0	1·11	0·77	2·9	1·1	100	5·3

Manchester.

Dr. R. Veitch Clark reports that there were 82 cases of encephalitis lethargica, with 24 deaths. He points out that the incidence of puerperal fever has not fallen. There were 179 cases notified during 1925 as compared with an average of 113 for the preceding decennium. Puerperal infection is being treated in Monsall Hospital by lymph drainage of the uterus, and this method is combined with chemotherapy and transfusion of immunised blood for the acute hæmic infections. The results from the lymph drainage treatment were uniformly satisfactory; all the fatal cases except one were desperate from the moment of admission. Attention is drawn to the sharp rise in the respiratory deaths coinciding with the November fogs, and the present position with regard to the proposed regional smoke-abatement committee is indicated. The Ministry of Health is to be asked to make an order forming a joint district. The area will be divided into inspection districts on the basis of 200 to 250 chimneys per district. Each district will be governed by a committee elected from the health committees, and each inspection district committee will elect two members to form the regional council, which will formulate the policy for the whole region. There will be some 20 inspection districts in the region, and at the outset the present executive committee are not prepared to make definite recommendations with regard to the domestic smoke problem. At the end of 1925 a scheme for reorganising sanitary inspection came into operation. The chief change will be the abolition of a number of special inspectors; overlapping and dual visiting will be avoided, and the work of the district inspectors will become more interesting and varied.

Dr. Clark refers to the need for daily clinics for venereal disease, with facilities for intermediate treatment at all times of the day. The unification of clinical control and the provision of maternity beds for pregnant women also require attention. Plans have been approved for the provision of 210 beds at Abergele Sanatorium for the treatment of children suffering from tuberculosis. The report gives much detailed information about methods of treatment adopted at the various hospitals, including experience of the Schick, Dick, and Schultz-Charlton tests, the following up of patients tested with tuberculin during the years 1919 to 1923, the value of the Weiss urochromogen reaction in pulmonary tuberculosis, &c. Lieut.-Colonel J. W. Brittlebank, the chief veterinary officer, reports that the milk supply of 292 farms situated outside Manchester was examined for tubercle and that 8·2 per cent. of the samples were tuberculous. Farmers, he thinks, are getting to understand what is meant by cleanliness, but he is not hopeful of great results until steam sterilisation plant is in general use. The sale of graded milks makes little headway in Manchester. Colonel Brittlebank believes that at least half the milk distributed in Manchester is rendered safe for the consumer by pasteurisation. Dr. Clark shows that the building of houses during the past few years has not kept pace with the natural increase of the population. He mentions three standards for the measurement of overcrowding—viz., the Registrar-General's, of more than two persons to a room; the Manchester standard, of more than two and a half persons per bedroom (two children under ten being counted as one person); and his own, of conditions in houses which prevent the proper separation of the sexes for sleeping purposes. Under the first standard he estimates that 8000 families are overcrowded, under the second 25,000, and under the third 29,000. The total number of families in the city at the time of the 1921 census was 163,939. Dr. Clark's final estimate is that the number of new houses required by the end of 1926 is 17,622.

An account is given of the work of the Manchester Committee on Cancer.

Salford.

Dr. H. Osborne reports the opening of a municipal maternity home and babies' hospital, with room for ten maternity cases and 18 babies. All the maternity cases attend a special ante-natal clinic. The great need of the maternity and child welfare scheme is for better accommodation at the centres. At present there are two primary and seven subsidiary centres. All are inadequately housed, and Dr. Osborne's recommendations include the provision of three primary centres, if possible in the same buildings as school clinics, and six subsidiary centres. It is pointed out that the density of the population of Salford is far greater than that of any other Lancashire town. There is no suitable building land left, and Salford is hemmed in on every side by growing urban districts. There are 3000 people clamouring for houses, but the great majority can never be housed in Salford. Since 1913 the panel practitioners of Salford have been remunerated on an attendance basis. The only districts with a similar scheme are Manchester and the Isle of Man. From Jan. 1st, 1927, the capitation system will be adopted in Salford.

With a view to smoke abatement, the classes for stokers at the Salford Technical College are to be continued. The Health Committee has also decided to abolish the permissible limit of three minutes' dense black smoke in the half-hour and to consider each case on its merits. Dr. Osborne points out, however, that domestic smoke is the more serious part

of the problem, and that "when this country decides that coal must be carbonised before being burnt then smoke inspectors will lose their jobs." He has experimented during the year with fire-brick grates of the well type and dry gas coke from vertical retorts, and finds that this type of coke gives a beautiful radiant fire and heats the room somewhat better than coal and at two-thirds only of the cost. The report gives full details of these experiments, and also of experiments on chemical disinfection, which show that disinfecting power increases directly with the temperature; for example, the same solution of phenol is about three times as powerful a disinfectant at blood heat as it is at freezing point.

The bulk of the milk comes from farms in Cheshire, Lancashire, Yorkshire, and Derbyshire. Of 331 samples from the outside farms 29, or 8·75 per cent., contained tubercle bacilli. This corresponds closely to the Manchester percentage of 8·2. The towns get their milk from similar sources. The tuberculous milks were successfully followed up, as on 26 of the 29 farms visited 30 cows were found with tubercle of the udder. In the three remaining farms cows had been removed between the taking of the sample and the date of inspection. Midwives attended 3445 of the 4597 births, and sent for medical aid in 1428 of their cases. There have been several recent outbreaks of pemphigus neonatorum. Each outbreak has been confined to a certain area, and it has been impossible to trace any cause. From June, 1924, to the end of the year there were 79 cases, with 11 deaths. The disease has been compulsorily notifiable in Salford since March, 1926.

Bolton.

Dr. C. W. Paget Moffatt reports that a scheme for the conversion of the principal sewage works from chemical precipitation to the bio-aeration system at an estimated cost of £74,500 has been approved by the Ministry, and is now in progress. The original intention was to provide four acres of filters for the further treatment of the effluent, but this portion of the work has been postponed for 12 months in order to ascertain whether there is any necessity for this final filtration. For smoke abatement Dr. Moffatt, like Dr. Osborne, pins his faith to smokeless fuel. He draws attention to the prevalent practice of firing the chimneys of dwelling-houses instead of having them swept, thus creating a nuisance to the neighbours "very much worse than that caused by any factory chimney." He wishes the magistrates would take a more serious view of this offence. Bolton's housing problem is exceptional. The population is now the same as it was at the census of 1911, when there were 41,585 houses with 4·34 inhabitants per house. In 1925 there were 44,193 houses with 4·08 inhabitants per house. The population was the same, but there were more and smaller families. It is difficult to say how many extra houses are needed; 1500 applications have been made, but Dr. Moffatt thinks that not more than half of them are genuine. It is waste of time to theorise about the number required. Houses should be turned out in batches of 100, and this process should continue so long as they are absorbed. All the cases of overcrowding to which attention was drawn in 1925 were abated. There are several small unhealthy areas. To deal with these would involve the demolition of 200 houses. There are 1000 back-to-back houses, and the conversion of each pair into one through house would involve the loss of 500 more houses. Street improvements will involve the demolition of a few more. Dr. Moffatt estimates that 800 houses are required to compensate for these three prospective causes of shortage. The public analyst for the borough, Mr. H. Hurst, thinks that the standard for Grade A milk is much too lenient, and suggests a count of 50,000 and *B. coli* absent in 1-10th of a c.cm. Boric acid is still being used extensively. Thus it was contained in five out of eight samples of potted meat, in six out of seven samples of mincemeat, and in all the samples of margarine (13), lemon-cheese (7), cakes (6), and fruit salad (1).

In 1924 there were 40 cases of encephalitis lethargica, with 17 deaths, and in 1925 23 cases, with 13 deaths. During the five-year period ending with 1925 there were 74 cases notified, with the following result according to inquiry made June, 1926:—22 deaths; 1 committed suicide; 5 died from other diseases; 23 made a complete recovery; and 23 are mentally impaired. The attendance of women at the clinic for venereal diseases is discouraged by the inadequacy of the premises. Plans have been prepared for a new clinic.

Derby.

Dr. A. E. Brindley reports that the failure to rid the borough of small-pox quickly was chiefly due to the refusal of the contacts to be vaccinated. Less than 9 per cent. of the persons in the home, who had been in more or less intimate contact with the patient, were vaccinated or revaccinated. There were 746 notifications of small-pox during the year, with no deaths. There were no serious complications except in the case of a baby who lost the sight of one eye. It was estimated in June, 1926, that the epidemic had cost the borough about £15,000. Dr. W. H. Wray, the tuberculosis officer, thinks the results from the treatment of adult pulmonary tuberculosis are so unsatisfactory that efforts should be concentrated on dealing with the children. Although it takes considerable time and persuasion to obtain sputum from children with evidence of bronchial irritation, tubercle bacilli were, nevertheless, found in the sputum of 50 children during 1925. During the past two years Dr. Wray has observed a more virulent type of pulmonary tuberculosis with very rapid lung infiltration. Arrangements are being made for the admission of non-pulmonary tuberculosis to Bretby Hall Orthopædic Hospital. Dr. Wray would like to see allotments provided for tuberculous patients, each with a shelter. If the patients were induced to spend all day on the allotment and to do some gardening under supervision the results, he thinks, would be less costly and more satisfactory than those of sanatorium treatment.

A special clinic was provided in September for the supervision of ailing children between the ages of 2 and 5 years. The total of births was 2527, but only 188 expectant mothers attended the antenatal clinic. There is much overcrowding, although the council have provided 1020 dwellings in the last five years. The demand for Grade A milk has increased from 13½ gallons daily at the end of 1923 to 33¼ at the end of 1925—not a sensational increase. Among suggestions for the future Dr. Brindley includes the provision of more playgrounds for small children, in view of the increasing danger of the streets, and more rapid progress with the conversion of tub closets and privy middens. At the end of 1925 there were still 1968 tub closets and 203 privy middens.

St. Helens.

Dr. Frank Hauxwell shows that his borough is very well supplied with open spaces and parks, but that there are several congested areas which require opening out and replanning. Charts show the decline of the birth-rate from 46 to about 24, and of the death-rate from about 25 to 12 during the last 50 years, and of the infant mortality-rate from 180 to 100 in the last 25 years. The old small-pox hospital has done good service by providing 10 beds for maternity cases and 20 for ailing infants. Arrangements have now been made for the treatment of maternity cases at the new maternity block of the St. Helens (Voluntary) Hospital, which has 15 beds, and for the ailing babies to be treated at the isolation hospital. Progress in the reduction of the shortage of houses is very disappointing. Since 1914 the population has increased by 8825, but only 880 houses have been built. An orthopædic scheme has been approved. Besides an orthopædic centre in St. Helens, six beds will be subsidised at the Liverpool Children's Hospital and six at the open-air hospital for children at Leasowe.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDING NOV. 27TH, 1926.

Notifications.—The following cases of infectious disease were notified during the week: Small-pox 313 (last week 353), scarlet fever 1985, diphtheria 1185, enteric fever 51, pneumonia 1031, puerperal fever 49, puerperal pyrexia 140, cerebro-spinal fever 9, acute poliomyelitis 55, acute polio-encephalitis 6, encephalitis lethargica 61, continued fever 1, dysentery 6, ophthalmia neonatorum 154. There were no cases of cholera, plague, or typhus fever notified during the week.

The total number of cases of acute poliomyelitis and polio-encephalitis taken together—namely, 61—is again substantially higher than the previous week, 10 cases having again been notified from the County of London, all of them on the south side of the river, 5 from Leicestershire (Leicester 3, Hinckley and Ashby-de-la-Zouch 1 each), 3 from Notts (Nottingham 2, Stapleford R.D. 1), 4 from Surrey (four separate districts), 5 from Warwick (Birmingham 3, Coventry 1, Rugby R.D. 1), 3 from Wilts (Salisbury 2, Tisbury R.D. 1), 3 from Yorks West Riding (Conisborough 1, Harrogate 2), 3 from Glamorgan (Cardiff 1, Merthyr 1, Neath R.D. 1), the remainder in ones and twos from many other counties. (Any return from Rutland is missing.)

Of the 313 cases of small-pox, 250 were reported from the county of Durham (the chief areas being Brandon and Byshottles 60, Crook 12, Hetton 12, Jarrow 16, Shildon 11, Willington 27, Chester-le-Street 25, Lanchester 34, Sedgefield 11), 10 from Northumberland, and 46 from Yorks West Riding (Sheffield 14, Mexborough 16, and small numbers from eight other areas).

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 4 (1) from enteric fever, 8 (0) from measles, 4 (1) from scarlet fever, 22 (4) from whooping-cough, 46 (16) from diphtheria, 69 (17) from diarrhœa and enteritis under 2 years, and 52 (8) from influenza. The figures in parentheses are those for London itself.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. G. D. Bateman is placed on the Retd. List with the rank of Surg. Capt.

ROYAL ARMY MEDICAL CORPS.

Capts. G. D. Yates, F. M. Lipscomb, H. P. Rudolf, and D. N. Macleod to be Majs.

Temp. Capt. J. F. P. Gallagher relinquishes his commn. and is granted the rank of Lt.

TERRITORIAL ARMY.

Col. A. D. Ducat to be Hon. Col. 56th (1st Lond.) Div.

Lt.-Col. (Bt.-Col.) F. Darlow from the Gen. List, R.A.M.C., to be Col.

Capts. I. H. Lloyd-Williams and W. L. R. Wood to be Majs.

Capt. (Prov.) G. A. Fisher is confirmed in his rank.

Capt. G. T. Symons (late R.A.M.C.) to be Lt. and relinquishes the rank of Capt.

ROYAL AIR FORCE.

Flight Lt. G. R. Hall relinquishes his temporary commission on ceasing to be employed.

RESERVE OF AIR FORCE OFFICERS.

W. G. Weston is granted an honorary commission as a Flight Lt.

INDIAN MEDICAL SERVICES.

To be Temporary Lieutenants.—Parduman Singh and Mangalore Narasimha Pai to be Temp. Lts.

Lt.-Col. J. E. Clements on return from leave to resume charge of his duties as Inspector-General of Prisons, United Provinces. Lt.-Col. C. E. Palmer, Officiating Inspector-General of Prisons, United Provinces, is posted to Allahabad Central Prison as Superintendent. The services of Dr. Muhammad Umar, medical officer, Central Prison, Allahabad, are placed at the disposal of the Inspector-General of Civil Hospitals, United Provinces. Lt.-Col. R. F. Baird, civil surgeon, Allahabad, to officiate as Inspector-General of Civil Hospitals, United Provinces. Dr. B. K. Mukharji, Provincial Medical Service, medical officer in immediate charge of the Colvin Hospital, Allahabad, to officiate as Civil Surgeon in addition to his own duties. Lt.-Col. R. F. Baird, Officiating Inspector-General of Civil Hospitals, United Provinces, has been nominated by the Governor to be President of the United Provinces Medical Council.

Correspondence.

"Audi alteram partem."

SPIRITUAL HEALING.

To the Editor of THE LANCET.

SIR,—We the undersigned medical members of the Archbishop of Canterbury's Advisory Committee on Spiritual Healing should be grateful to any medical practitioner who could supply us with information regarding patients who had received benefit from spiritual healing, whether through an organised Mission of Healing or individually. We appreciate that names could not be given without the permission of the patients concerned and, although we should like to have them where consent is given, we should nevertheless be glad to receive any information which can properly be supplied, as the desire of the Committee is to collect evidence as to the value of spiritual healing and the type of person most likely to be helped by it. Letters may be addressed to any of the signatories.

We are, Sir, yours faithfully,
WILLIAM BROWN,
H. CHARLES CAMERON,
J. WALTER CARR,
W. MCADAM ECCLES,
PERCIVAL H.-S. HARTLEY,
Dec. 6th, 1926. MAURICE CRAIG (Hon. Sec.).

GANGRENE OF THE TOE.

To the Editor of THE LANCET.

SIR,—There is no surgical affection which demands less surgical intervention than the gangrenous toe of a senile or degenerate subject. The term operation should be forgotten in all cases in which after a few days' tentative treatment the gangrene shows a tendency to remain at a standstill, indicating that there is still some circulation existing just proximal to the lesion, and it may be taken as certain that any kind of local traumatism including chemical irritation will be detrimental to Nature's efforts to form a line of demarcation.

Everything possible should be done to raise the patient's power of resistance by nutritious food with discreet use of alcohol, by (when feasible) continuous sojourn in the fresh air, with limb enveloped in wool and crêpe bandages comfortably placed in a well-padded wire cradle, with footpiece at right angle, and elevated in a Salter swing in a bed in which an electric heating cage may be placed at convenience.

During the initial period, when the gangrene is moist, bathing three times daily with non-irritant disinfecting lotions such as warm peroxide (1 in 17), warm carbolic (1 in 70), plus warm corrosive sublimate (1 in 3000) fomentation (without any impermeable dressing) is very helpful. Later, when fœtor and discharge have ceased, and the part appears mummified, painting daily with tinct. benzoin. co. has proved useful, and afterwards when the "sappers" have (with output of serum) established their trench proximal to the line of gangrene, weak boric foments have been found a satisfactory dressing until the involved phalanx becomes sufficiently detached so that with gentle manipulation it may be extracted with forceps like a loose tooth. Having reached this favourable stage there must be no attempt to hasten convalescence, the limb should be kept in absolute rest on splint until the stump has firmly healed. The internal administration of opium in these cases is time honoured; 1 gr. of codeia three times daily appears helpful, and digitalis with strychnia may prove a useful addition.

All this applies solely to cases of gangrene with obvious tendency to limitation, and to those not handicapped by any grave form of general toxæmia. In the latter there is only one chance—viz., amputation through lower third of thigh, and the sooner it

is performed the better. In those cases in which Nature is unable to isolate a dead toe, it may be reckoned as fact that *any* operative intervention at the primary lesion or between it and the main arterial trunk is a waste of time.

I am, Sir, yours faithfully,

Buenos Aires, Nov. 10th, 1926. JOHN O'CONOR.

MEDICAL SCHOOLS AND THE LONDON UNIVERSITY BILL.

To the Editor of THE LANCET.

SIR,—In the Committee stage of the University of London Bill last Thursday, the Government added an amendment which has the practical effect of exempting any theological college which desires exemption from the operation of the regulations proposed regarding the selection of teachers in schools. I regret that the medical schools had not thought it worth while to ask for the same privileges. I cannot think that the medical schools will appreciate the necessity of submitting appointments of their medical and surgical staff to the new Council of the University, upon which they may have no representation whatever, and which will be largely a body unfamiliar with the special needs of hospital schools.

Sir Wilmot Herringham, in his interesting letter to you, thinks that nothing is to be feared from the Crown and the London County Council representatives, and it is the fact that they have not, with one or two exceptions, hitherto taken a very considerable part in the activities of the Senate. I submit, however, that the position will be totally changed with the representation of these bodies increased fourfold, as it will be, upon the future Council of the University. Surely the genesis of the Departmental Committee itself, as an offspring of the Haldane Commission, makes its recommendations rather more significant than they otherwise might be. It was frankly the aim of the Haldane Commission to introduce State control of the University upon the German pattern, and to this end they provided a representation of six members of the Crown and the London County Council out of 15 upon their supreme executive body which they called the Senate. Exactly the same proportional representation of these interests is reproduced by the Department Committee Report. We are, I think, likely to get under these circumstances an entirely new type of representative from the Government and from the London County Council. The future Council will have the only real power in the University. The proportion of educational representatives will, as Mr. Lees-Smith plainly stated in his Minority Report, allow of only a bare majority of Senatorial representatives, and if there is any disagreement between such representatives, the outside members, as one may call them, will exercise a very real control.

Sir Holburt Waring, I think, takes a wiser standpoint than Sir Wilmot Herringham, in the objection he makes to the preponderant academic representation upon the Senate. He is reported to have declared as his opinion that "There are too many academic representatives on the Senate, and they will quarrel among themselves as to how the spoils are to be divided." I find it difficult to understand why Sir Wilmot Herringham should consider the future Council any more impartial than the present Senate, more especially as with the composition of the new Senate and the very preponderant influence of the collegiate representatives, it is inevitable that a large number of heads of colleges will be members of the future Council, and we shall again have the anomalous position that members of the Council will have to decide questions in which they themselves are financially interested on behalf of their colleges, and the "dog-fight" that Sir Holburt Waring foresees cannot fail to occur.

I am, Sir, yours faithfully,

E. GRAHAM LITTLE.

Wimpole-street, W., Dec. 6th, 1926.

SUNSHINE MEASUREMENTS.

To the Editor of THE LANCET.

SIR,—May I draw your attention to a confusion of terms which may lead to a confusion of thought. The *Times* of Nov. 25th, referring to the weather of the 24th, speaks of "Sunlight (ultra-violet rays) figures" at Kingsway 0; at Ventnor 5½. These measurements were made with an acetone-methylene-blue colour test which does not react to light rays, only as is claimed to ultra-violet rays. These, I submit, should not be called sun*light*, but the sun's ultra-violet rays. Why on the 24th there should have been none at Kingsway I know not; here at Putney it was bright sunshine all day long, but at Ventnor there were 5½ units. This brings me to another point. How many units is the maximum for Ventnor in November? From the *Times* of Dec. 22nd, 1924, I infer that the maximum for July is 24; but we might be told. Nov. 25th, 1926, was a very foggy day; there was no ultra-violet light at Kingsway, or at Lowestoft, and only 2 units at Ventnor. On the 26th we were given the hours of sun*shine* on the 25th at various health resorts. These resorts advertise their hours of sunshine, and perhaps we shall have Ventnor advertising its ultra-violet "light" as much more important than sun*shine*.

Ultra-violet light is said to play an important part in ordinary photography; a lens may stop it to some extent, but it is possible to take photographs through a pinhole without a lens. Photographers have their own strips of sensitive paper for testing the light, but they are not standardised. The rapidity of plates is standardised by the Heuber and Driffield method. There are five million elementary school-children in England, and as far as preventive medicine is concerned most of them are dependent on the rays of the sun, so these rays are fairly important.

I am, Sir, yours faithfully,

WALTER EDMUNDS

Putney, Nov. 26th, 1926.

*** We agree with Mr. Edmunds that the figures are unintelligible to the reader when no standard of comparison is given. There seems little doubt that a sunny day in London may give no reading at all on the Leonard Hill test meter.—ED. L.

THE TREATMENT OF FLOUR.

To the Editor of THE LANCET.

SIR,—I have just read the letter of Mr. W. Jago in your issue of Nov. 13th, in which he traverses certain statements by Mr. G. D. Elsdon, public analyst, on the above subject. It appears to me that Mr. Jago misses the main point in this all-important matter of the adulteration of one of our staple articles of food. Persulphates and other chemicals are foreign additions to flour, and whatever their bad or supposed good qualities, they constitute, when added to flour, substances which render this food *not of the nature of flour*. At the very least, therefore, the public is surely right in demanding that the presence of all such foreign substances should be declared to the purchaser, and the public analyst is doing good service to the community in guiding public opinion on this question. I know of no clearer rights that the consuming public should have, if indeed it does not possess them, than the right to a normal article, coupled with the right to demand that it shall know what it is buying. This right of the consumer has now been conceded, in the case of preservatives, by the new Preservative Regulations, and it is an eminently reasonable thing to ask for its extension to the whole range of foods, but especially to that staple food—flour—which is in daily use in every household in the form of bread.

I am, Sir, yours faithfully,

ARNOLD R. TANKARD.

The City Laboratories, Hull, Dec. 1st, 1926.

THE DISSOLUTION OF INSULIN.

To the Editor of THE LANCET.

SIR,—In view of Dr. R. D. Lawrence's interesting letter I am pleased to give to readers of THE LANCET a few more details of my recent work.

Commercial insulin seems to be composed of at least three substances—viz., the true pancreatic hormone A, the anti-insulin B, and co-insulin C. Of these substances A and B have been obtained in crystalline form, while the work on the substance C is only now nearing completion, and cannot be reported on at present.

Substance A, as Dr. Lawrence rightly states, acts on rabbits according to their fasting blood-sugar levels. It increases the blood-sugar generally in those with a low level and decreases it in those with a high level. In over 20 cases of diabetics, treated so far in Warsaw clinics and elsewhere, it could be ascertained that the substance A acts like the old insulin. It is too early, however, to state whether the new substance presents any disadvantage or advantage over insulin, but since it is free from the very toxic substances contained in commercial insulin the latter should be the case. In non-diabetics, on the contrary, the substance A causes either no change in the blood-sugar or appreciable increase. One exception was noted here; this was a case with normal blood-sugar level, but with sugar in the urine one week before injection of substance A. This interesting result suggests, perhaps, that the substance A might be used with success for diagnostic purposes, like the known sugar tolerance-test, but it might be of more value to the physician than the latter.

One word more on the puzzling behaviour of substance A in diabetics and non-diabetics. My present explanation is that in non-diabetics there is lack of substance C (co-insulin), without which, perhaps, the substance A cannot act, or a superfluity of substance B (anti-insulin). In diabetics, on the contrary, there is too much of B (anti-insulin) and sufficiency of C (co-insulin). I am conscious, however, that this interpretation may have to be modified. Similar explanation can be put forward in Dr. Lawrence's interesting results (using ordinary insulin) on the blood-sugar increases in normal rabbits (which, personally, I never encountered with good insulin). In such cases the effect of insulin might depend on the ratio of substances A, B, and C in the preparation used, and on the equilibrium of these three substances in the animal itself.

I should like to take this opportunity to offer, for purpose of investigation, small quantities of my crystalline substance A to the clinics in Great Britain.

I am, Sir, yours faithfully,

CASIMIR FUNK.

The Biochemical Department, State School of Hygiene, Chocimska 24, Warsaw, Poland, Dec. 4th, 1926.

THE SUPPLY OF ARTIFICIAL LIMBS.

To the Editor of THE LANCET.

SIR,—We agree with the opinion expressed by Mr. Muirhead Little in your issue of Dec. 4th as to the importance attaching to the inspection of artificial limbs by a surgeon who has had experience in such work, and we noted with interest his suggestion to establish a small limb-fitting centre in Central London. At present it is the practice in hospitals for the surgeon to inspect the various limbs supplied, and it is of great assistance to the limb-maker that the surgeon who performed the operation and knows the case should consult with him as to its special needs. The inspection of finished limbs by the surgeon affords the limb-maker opportunity of demonstrating the construction of the particular limb, and of receiving from the surgeon suggestions dictated by his knowledge of the individual circumstances of the amputation. Our experience is that orthopædic surgeons are much more conversant with this subject now than in years gone by, and in cases supplied directly through hospitals or charitable institutions retaining the services of orthopædic surgeons there is little danger of unsuitable limbs being supplied. It would, however, undoubtedly be a boon to other civilian amputees if some plan existed by which the patient could enjoy the combined skill of surgeon and limb-maker, although we doubt whether the number of cases would warrant the establishment of a fitting centre. At the Queen Mary's Convalescent Auxiliary Hospital, Roehampton, the fitting is restricted to one or two firms, and the patient does not have a perfectly free choice of artificial limb. At Roehampton it is not possible to secure the services of surgeons who are free from the restrictions of Government contracts.

We are, Sir, yours faithfully,

W. R. GROSSMITH, LTD.

12, Burleigh-street, Strand, W.C., Dec. 6th, 1926.

CYCLIC VOMITING.

To the Editor of THE LANCET.

SIR,—In your issue of Dec. 4th appears an annotation under this heading, in which, after some introductory remarks—not, I think, representing current pediatric opinion very accurately—we are introduced to the views of an American radiographer who has found in children suffering from this disorder a high proportion of "ptosed stomach" and of "elongated colon." Perhaps a more suitable text for commentary might have been found in the valuable paper by Graham and Brown in the current number of the *Archives of Disease in Childhood*, in which references will be found to much of the recent work on ketonæmia, ketonuria, and ketogenesis—work which has shed a flood of light on the whole question, and to which no reference is made in your article.

All children—and quick, eager, excitable children, with a high metabolic rate, more than others—respond to certain forms of stress, to infection, to starvation, to great exertion, to excitement, to anæsthesia, and to a diet with a high proportion of fat and a low proportion of carbohydrate, by the development of ketonæmia, with diminution in the alkaline reserve of the blood, and a transitory fall in the blood-sugar. In practice it is apparent that these are precisely the factors which determine an attack of so-called cyclical vomiting in susceptible children. Especially the factor of infection is of importance. The ordinary cold running through a nursery will determine a simple rhinitis in the rest of the children, in the child so pre-disposed the underlying infection will be obscured by a typical "sick attack." Yet it may be that a precisely similar disturbance is produced by the stress of an examination or by a long railway journey.

In the administration of glucose, with or without insulin, we have in our hands a treatment which is on the whole strikingly effective. In prophylaxis some consideration, and it may be some modification, of the balance of fat and carbohydrate in the diet is very necessary, although not more necessary than the extirpation of any source of recurrent infection, whether, very rarely, in the appendix, or, very often, in the tonsils. The response of different children to comparable infections is very various, and the metabolic component of the disturbance, and the infective component, are often inextricably intertwined.

Recent studies in metabolism have shown that the normal child possesses the power of drawing largely upon its own carbohydrate reserves to complete the oxidation of the fat in its diet, thus metabolising a mixture very different from that ingested; and it would seem that in the child with cyclical vomiting this power is less evident. The tendency to "cyclical vomiting" is to be explained by some fault in carbohydrate metabolism, although we are still ignorant of the precise nature of that fault. I think we may take it that the length of the colon is of less significance.

I am, Sir, yours faithfully,

H. CHARLES CAMERON.

Devonshire-place, W., Dec. 6th, 1926.

RESEARCH AND MEDIOCRITY.

To the Editor of THE LANCET.

SIR,—In your excellent account (THE LANCET, Nov. 27th, p. 1113) of the Society of Medical Officers of Health meeting to discuss research work in preventive medicine I am reported as saying: "The man who depended on research for his initiative was not likely to achieve more than mediocrity." My actual words were: "Unless a worker has initiative of his own, and thinks for himself, I doubt the value of his work. Anyone dependent on advice for his actions will never achieve anything beyond mediocrity."

I am, Sir, yours faithfully,

Paignton, Dec. 4th, 1926. E. WARD.

Medical News.

UNIVERSITY OF LONDON.—Prof. H. R. Kenwood Sir William Simpson, and Sir Holburt Waring have been nominated Governors of the London School of Hygiene and Tropical Medicine.

UNIVERSITY OF DUBLIN, SCHOOL OF PHYSIC, TRINITY COLLEGE.—At recent examinations the following candidates were successful:—

FINAL MEDICAL EXAMINATION.

Part II., Medicine.—Edward G. Montgomery, Margaret H. Donaldson, Edmund P. N. M. Early, John C. T. Sanctuary, Menzies L. M'Cauley, Silver M. E. Deane-Oliver, John B. Patrick, Desmond Blewitt, Rachel E. Porter, James J. FitzGerald, Robert Kahn, Solomon Gurevich, John O. Bennett, Henry A. Ferguson, Robert A. J. Holmes-Ievers, John Quigley, Geoffrey D. Edwards, Charles F. M. Wilson, Myer Hoffman and Kathleen R. Byrne.

Surgery.—Victor St. G. Vaughan, Lionel B. Somerville-Large, Edward H. Harte, Victor G. Horan, Arthur J. Conlin, Stella C. Ross, Annette K. Wood-Martin, Edmund P. N. M. Early, Edward W. Bingham, Edward G. Montgomery, Arthur N. B. Odbert, Norah M. Smith, Arthur R. Gray, Andrew E. A. O'Byrne, John B. Patrick, Daniel A. O'C. Quinlan, Edward A. Ellis, Rachel E. Porter, Wilhelm F. Knobel, Gladys L. Craig, John Johnston, John J. O'Dwyer and Charles F. M. Wilson.

Midwifery.—Wilfred F. Lane, Lenox R. S. MacFarlane, Robert S. F. Hennessey, Thomas C. M. Corbet, Shirley D. K. Roberts, Wilfreda D. C. T. Pigott, Gilbert M. Smith, Isidore Isaacson, Patrick Brangan, George H. Henry, John H. Stephens, Maurice F. N. Griffin, Charles L. Day, Christina M'Donald, Ethel M. Weir, Louis R. Brumberg, Hubert C. Weir, George M'Donald, Samuel R. Elmes, Daniel M. Briuk, Albert Sachs, Thomas J. O'Reilly, John O. Bennett, Andrew C. C. Charles, Samuel B. Dalrymple, Norah W. Brown and Cecil F. Cope.

Master in Obstetric Science.—Frederik W. Pienaar.

BOARD OF CONTROL.—The address of The Board of Control (Lunacy and Mental Deficiency) England and Wales has now been changed to Caxton House West, Tothill-street, Westminster, S.W.1. The telephone number is Victoria 8540.

THE Eighth Edition of Treves's "Surgical Applied Anatomy," revised and enlarged by Prof. C. C. Choyce, is announced for early publication by Cassell and Co. Ltd. It includes a number of new illustrations.

ROYAL INSTITUTE OF PUBLIC HEALTH.—The next congress of the Institute will be held at Ghent, in Belgium, during Whitsuntide (June 1st–6th), 1927. Delegates have been invited from the governments, municipalities and universities of Belgium, France, Italy, the United States of America, and other countries. The five sections will be devoted to: State Medicine and Municipal Hygiene; Naval, Military, Air, and Tropical Diseases; Industrial Hygiene; Pathology, Bacteriology, and Biochemistry; and Women and the Public Health. Special arrangements have been made for travelling. Full particulars may be had from the hon. secretaries of the Congress at 37, Russell-square, London, W.C. 1.

THE LATE DR. A. H. BUTCHER.—Dr. Arthur Herbert Butcher, who died suddenly on Nov. 25th, at the age of 71, had practised in Birkenhead for nearly 40 years. Born at Ripon, he was the eldest son of the late Major-General Arthur Butcher, and was educated at the Royal Naval School, New Cross, London, at Queen's College, Cork, and at University College, Liverpool. He took the Scottish triple diploma in 1889. For 15 years he was consulting surgeon to the Birkenhead Borough Hospital, and he was the inventor of a number of devices used in surgical practice. During the late war he served for three years with a captain's commission in the Royal Army Medical Corps, and worked under the Ministry of Pensions. Dr. Butcher leaves a widow and daughters.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART. Arrangements have been made for the practice of the hospital to be open to undergraduates from Jan. 1st. One guinea will be charged for a one month's ticket, 2½ guineas for a three months' ticket. These fees are half those charged to graduates.

ROYAL INSTITUTION.—A general meeting was held on Dec. 6th, Sir Arthur Keith, F.R.S., Treasurer and Vice-President, in the chair. The Chairman announced that Prof. Julian Huxley had been elected Fullerian Professor of Physiology.—On Thursday, Dec. 16th, at 5.15 P.M., the Editor of THE LANCET will lecture on Medical Literature in Relation to Journalism.—On Tuesday, Dec. 28th, at 3 P.M., Prof. A. V. Hill will begin the Christmas course of juvenile lectures on Nerves and Muscles. Details of this course were given last week (THE LANCET, Dec. 4th, p. 1194).

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN.—The annual dinner of the School and Hospital was held on Thursday, Dec. 2nd, at the Savoy Hotel, London, Lady Barrett, the Dean, presiding over a large number of doctors connected with the institution, their friends, the students and representative guests.

Sir John Rose Bradford, in proposing "Prosperity to the School and Hospital," regarded them as indivisible, and testified to the spirit prevailing at the Royal Free and all other hospitals with teaching schools attached, as something indefinable, a something existent in public schools and university colleges and found nowhere else. With regard to the voluntary system, on which the Royal Free and the other like charitable institutions of the country depended, he said that the serious threat to this system, following upon the pecuniary conditions produced by the war, had largely disappeared, leaving the system more stable than ever, based alike upon the generosity of the public and upon the freehanded service given by medical staff and lay authorities—in which connexion he referred warmly to the devoted work of Lord Riddell, the present Chairman. A school like that connected with the Royal Free, he said, having a creditable past and a promising future, was sure to progress, while he hoped that every opportunity for scientific research would be taken, because that was the surest way to march forward. He coupled the toast with the name of the Chairman, and reminded his audience how onerous the duties of the Dean of a medical school were when faithfully discharged.

Lady Barrett, in reply, made reference to the recent death of Dame Louisa Aldrich-Blake, the late Dean of the school, and expressed the regrets of all concerned with the hospital and school at the retirement of Dr. William Branson. She testified warmly to the services of Prof. Lucas Keene, the Sub-Dean, to whom, she added, the organisation of the dinner was due, and then spoke of recent devleopments in the institution, such as the forthcoming orthopædic department, the new children's wards, soon to be opened by Her Majesty the Queen, and the acquisition of a sports ground. Lady Barrett concluded by alluding with satisfaction to the fact that more of the students of the London School of Medicine for Women were entering general practice, perhaps as a result of the bar to marriage found in some of the public services. To-day, as general practitioners, she said, they would find opportunities for a full and useful life; they could teach preventive hygiene through the best of all mediums—the management of the home; while opportunities were now afforded for post-graduate education, and cottage hospitals were springing up to assist in clinical practice.

The toast of The Guests was proposed in a witty manner by Mr. Ulysses Williams, and replied to by Mr. T. F. Sibly, D.Sc., the new Principal Officer of the University of London, and Miss E. C. Lodge.

Dr. Sibly spoke of the great responsibilities which he had undertaken in connexion with so immense a University at a time when new efforts to organise and correlate its activities were finding expression in a Bill that showed every sign of being passed. He signified his gratitude for the manner in which he had been received at the various schools of the University which he had visited, and, referring to post-graduate education, he thought, that in spite of the work now being done, there was room for great developments.

Miss Lodge, speaking as an historian, said that a new connexion between the study of history and that of medicine had lately been brought home to her by the widely held view that medical conditions must have largely influenced both the character and behaviour of historical protagonists, and the health conditions in which the work of the world had to be done. She viewed with apprehension the necessity of learning medicine when no longer of student age, and considerably amused the company by detailing some monstrous mediæval receipts as constituting examples of medical history.

The health of the Chairman was proposed by Dr. Mary Blair, who spoke eloquently of the reliance which all her juniors placed upon Lady Barrett's scientific skill and uniform kindness. The evening closed with dancing.

QUEEN'S HOSPITAL FOR CHILDREN.—In his speech at last week's dinner of the Queen's Hospital for Children, Hackney-road, the Duke of York, who presided, stated that the two largest wards, containing 62 beds, would have to be closed at the end of the year unless a large sum were raised at once. Towards the £20,000 asked for, about £7000 had been obtained.

RADIUM FOR ADDENBROOKE'S HOSPITAL CAMBRIDGE.—A report from the medical staff emphasises the urgent need for a supply of radium. The minimum quantity necessary to make a start in treatment is 62 milligrams, which, at £11 10s. per milligram, comes to £713, and the cost of screens and other appliances would bring the total up to £943.

INTERNATIONAL MEETING AT FRANZENSBAD.—Following the precedent of last year, an international meeting of medical practitioners interested in cardiology and gynæcology will be held at Franzensbad from May 22nd to 26th next. Addresses on the present state of these branches of science will be given by well-known medical men.

THE SCHWEIZERISCHE MEDIZINISCHE WOCHENSCHRIFT.—Dr. Eugen Bircher, of Aarau, has been appointed co-editor with Prof. Alfred Gigon, of Basle, of this publication, in succession to the late Dr. Max Fingerhuth, of Zurich. Dr. Bircher is chief surgeon at the Aarau Cantonal Hospital, and is well known in Switzerland as an original writer on medical and medico-political matters.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.—On Nov. 27th (THE LANCET, p. 1139) we published a statement received from the secretary of the College, announcing that the Alvarenga Prize for 1926 had been awarded to Dr. P. S. Pelonze and Dr. F. S. Schofield for an essay entitled The Gamophage. We have since been informed that the title of the essay was The Gonophage.

DAVID LEWIS EPILEPTIC COLONY.—At the annual meeting of the David Lewis Manchester Epileptic Colony at Warford, Cheshire, it was stated that the daily average of colonists in residence was 373, and that there is a long waiting list. The 82 beds placed at the disposal of the Ministry of Pensions for ex-service men remains in full occupation.

HASTINGS DISPENSARY.—After redecoration and improvement, including the addition of a small operating department, the Hastings Dispensary, situated in the old part of the borough, has been reopened. It was established 95 years ago, and it is doing valuable work among the poor; it has been the means of relieving the Royal East Sussex Hospital to a considerable extent, and there is hope that it may soon be converted into a cottage hospital.

HARVEIAN SOCIETY OF LONDON.—The Buckston Browne Prize, consisting of a medal and the sum of £100, will be awarded for an essay on The Pathology, Diagnosis, and Treatment of New Growths Originating in the Walls of the Urinary Bladder. The prize is open to any member of the medical profession, under 45 years of age, who is registered in the British Isles or Dominions. Essays must be sent in by Nov. 1st, 1927. Further particulars may be had from the Hon. Treasurer, Dr. G. de Bec Turtle, 81, Cambridge-terrace, Hyde Park, W.2.

MAUDSLEY HOSPITAL.—The syllabus of lectures and practical courses for the Diploma of Psychological Medicine may now be had from the Director of the Central Pathological Laboratory, Maudsley Hospital, Denmark Hill, London, S.E.5. The first part of the course will begin on Jan. 4th, and includes lectures and demonstrations by Dr. F. Golla, Mr. S. A. Mann, Mr. Charles Geary, Dr. C. da Fano, and Dr. Henry Devine. The second part will follow in March, and the lecturers will include Dr. Bernard Hart, Dr. Edward Mapother, Dr. Golla, Dr. C. H. Bond, Dr. F. C. Shrubsall, Dr. Norwood East, Dr. A. W. Petrie, Dr. F. M. Walshe, and Mr. Foster Moore.

THE LATE DR. ALEXANDER HAMILTON.—Dr. Hamilton, who died at Edinburgh on Nov. 20th, came of a medical family and was born in Falkirk, where his father practised for many years. One of his brothers was the late Prof. David Hamilton, the first Erasmus Wilson professor of pathology in the University of Aberdeen. After studying at the Extra-mural Medical School at Edinburgh, Dr. Hamilton qualified in 1865. He went to Ashton-under-Lyne, Lancashire, as house surgeon at the District Infirmary in 1866 and was connected with the institution—as house surgeon, honorary surgeon, vice-President, and chairman of the medical board, and consulting surgeon—for 60 years. In Ashton-under-Lyne he had a large practice and for many years was certifying surgeon for Ashton and Hurst under the Factories and Workshops Acts. He retired from practice in 1915. Dr. Hamilton was a good violinist and an enthusiastic photographer. He celebrated his golden wedding in 1922.

A MEETING will be held at the residence of the Mayor of Lambeth, 193, Clapham-road, London, S.W., at 4 P.M. on Dec. 16th, when Dr. Camac Wilkinson will give an address on Tuberculin in the Diagnosis and Treatment of Tuberculosis.

A MANCHESTER WAITING LIST.—The Manchester Infirmary waiting list now reaches nearly 2000, mostly operation cases. It is impossible to take more patients until the nursing staff is increased, which cannot be until a new nurses' home is provided. The appeal for £150,000 to build such a home to accommodate 200 nurses, which was made a year ago, has produced little more than one-third of the sum needed, and the staffs in Manchester offices are being asked to contribute a penny a week per head towards providing the money.

ROYAL SUSSEX COUNTY HOSPITAL.—So many cases are now passing through the casualty department of this hospital, the great majority arising from the increasing motor traffic, that a house surgeon is to be appointed to have charge of the casualty department. At present there are three house surgeons and one house physician on the resident staff. In the 12 months ended Nov. 30th, 1925, the casualty department cases numbered 5612; in the 12 months ended Nov. 30th, 1926, the figure had reached a total of 7386.

UNIVERSITY OF LIVERPOOL.—Dr. W. S. Patton has been appointed to the Dutton Memorial Chair of Entomology. A medical graduate of the University of Edinburgh, he joined the Indian Medical Service in 1902, and retired with the rank of major in 1921. During the war Dr. Patton was entomologist to the Mesopotamian Expeditionary Force. He has acted as Director of the King's Institute of Preventive Medicine, Madras, and as Director of the Pasteur Institute of Southern India. Recently he has been engaged in entomological research in China, and has had charge of the Kala Azar Commission of the Royal Society.

VOLUNTARY HOSPITAL SYSTEM.—Speaking last week at a dinner given in support of the appeal for £25,000 for the extension of the London Jewish Hospital at Stepney Green, towards which £21,000 has now been raised, Sir Berkeley Moynihan said that the voluntary hospital system had never had its chance, and that if it perished it would be because of the lack of adequate organisation. The present situation was deplorable, and the 12,000 additional beds which were officially said to be needed might be multiplied by at least three if the inaugural symptoms of disease were to be dealt with adequately.

MEDICAL INSPECTION OF SCHOOL CHILDREN IN DUBLIN.—Little attempt has been made in any part of Ireland, writes our Irish correspondent, to carry into effect the provisions of the Medical Inspection of School Children Act of 1919, although these provisions were compulsory. As far as the area of the Irish Free State is concerned, only in two areas, both urban, is there medical inspection. It is now announced that a system of inspection is about to be established in the city of Dublin. It is estimated that the scheme will cost about £6000, of which half will be borne by central funds and half by the rates. It is intended to appoint two whole-time medical officers, who will work under the control of the medical officer of health. Arrangements for treatment will be made with the city hospitals.

SMALL-POX IN DURBAN.—Up to Nov. 17th there had been 13 deaths from small-pox in the Durban epidemic. The deaths were chiefly those of Indians, and so far there had been no deaths amongst Europeans. Many thousands of people had been vaccinated in Durban, largely Indians and natives, and over 4000 people had been vaccinated in the neighbouring city of Pietermaritzburg. Two cases of small-pox are also reported from Johannesburg, and they are believed to have been contracted from the infection in Durban. The publicity Durban is getting over the outbreak is far from welcome in view of the coming Christmas carnival.

THE LATE DR. S. C. NOBLE.—Dr. Samuel Clarke Noble, the oldest medical practitioner in Westmorland, died on Dec. 3rd, at his residence in Stricklandgate, Kendal, in his ninetieth year. He was a student at Middlesex Hospital, and qualified M.R.C.S. and L.S.A. in 1859. A member of a family which had produced doctors for three generations, he had an extensive practice in Lakeland, journeying mostly on horseback. He retired about a quarter of a century ago. In 1914, although well on towards 80 years of age, he volunteered for service in the war, and worked many hours a day examining military recruits in Westmorland, refusing remuneration for his services. He was a justice of the peace and Deputy Lieutenant of the County of Westmorland and in his younger days surgeon to the Kendal Hospital and H.M. Prison, Kendal.

Parliamentary Intelligence.

HOUSE OF LORDS.

TUESDAY, DEC. 7TH.

Births and Deaths Registration Bill.

THE Births and Deaths Registration Bill was read a second time.

HOUSE OF COMMONS.

WEDNESDAY, DEC. 1ST.

Street Collections for London Hospitals.

Sir ROBERT GOWER asked the Home Secretary whether he was aware that the operation of the regulations regarding street collections in the London Metropolitan area made by him on Oct. 1st last was such as to rescind the power possessed by the Commissioner of Police to grant permits for collections made on behalf of London hospitals and other charities by friendly society organisations in connexion with Sunday processions; and whether, having regard to the circumstance that such collections had been made for many years without inconvenience to the public and had resulted in considerable sums being raised for London hospitals, he would consider the desirability of amending such regulations to enable the Commissioner of Police to grant permits in such cases and subject to such conditions as he might think proper.—Captain HACKING replied: Before 1920 collections accompanying moving processions were entirely prohibited. In 1920 the Regulations were amended so as to allow collecting processions in special cases, but experience has shown that these processions are liable to cause so much disturbance and interference with traffic that it was decided to amend the street collection Regulations so as to prohibit the practice. My right hon. friend is sorry to have to put any obstacle in the way of collections for good objects, but the London traffic problem is now such that other considerations must be subordinated to traffic considerations.

Mosquito Pest at Singapore.

Mr. HORE-BELISHA asked the First Lord of the Admiralty what special work had been undertaken, and with what cost, towards mitigating the mosquito pest which had impeded the work at Singapore.—Mr. DAVIDSON (Parliamentary Secretary to the Admiralty) replied: The hon. Member is mistaken in supposing that the work has been impeded, since adequate steps were taken at the outset to prevent malaria by surface drainage and clearing. So far about £12,000 has been spent on these operations.

THURSDAY, DEC. 2ND.

University College Laboratory.

Captain ARTHUR EVANS asked the Secretary of State for the Home Department on what dates during the last five years the University College laboratory was inspected; and on how many of these occasions inspection was without notice; whether there were only two inspectors for the whole of Great Britain; and if he did not think that the inspection which it was desirable to have under this Act should be increased.

Sir W. JOYNSON-HICKS replied: There is a very strong tendency against such increases. The fact that this laboratory was visited 35 times in the last 18 months and 30 times without notice shows that the inspectors are doing their work very well.

Resignation of Chief Factories Medical Officer.

Mr. RHYS DAVIES asked the Home Secretary the reason why the chief medical officer of the factories department of the Home Office had resigned his post.—Sir W. JOYNSON-HICKS replied: The senior medical inspector of factories, having reached the pensionable age, applied to be allowed to retire, giving as his reason that he did not wish to be concerned in the administration of the Lead Paint (Protection against Poisoning) Bill; and I acceded to his application.

Mr. DAVIES: Is it not a fact that the pensionable age has nothing whatever to do with this resignation, and that it concerns mostly the point that this officer was at Geneva when this Convention was adopted, and that he feels now that, having negotiated the Convention, his honour is in question?

Sir W. JOYNSON-HICKS: I do not know about his honour. He had reached pensionable age. He retired because he did not agree with the views which I and His Majesty's Government have taken with regard to this matter.

Mr. DAVIES: Is it not true to say that this gentleman could have served the Home Office for one or two more years within the pensions scheme, but that he resigned as a protest against the action of the Government in regard to white lead poisoning?

Sir W. JOYNSON-HICKS: Certainly. I am expressing no opinion on the resignation. Possibly he could have served one or two more years, but he is quite entitled, if he so desires, to resign his position, which he has done.

Complaints against Panel Practitioners.

Mr. DAY asked the Minister of Health whether, in view of the number of complaints received from the contributors under the National Health Insurance Acts, he would consider an inquiry regarding the medical attention afforded panel patients.—Mr. NEVILLE CHAMBERLAIN replied: The efficiency of the medical service under the National Health Insurance Acts was exhaustively investigated by the Royal Commission, whose report, published early this year, contains a very favourable verdict. Comparatively few specific complaints are received by the Department, nor has anything come to my notice since the report which would justify the holding of any further inquiry.

Working-class Houses.

Mr. TREVELYAN THOMSON asked the Minister of Health the total number of working-class houses built since the Armistice; the number built under the various housing Acts; and the number in rural districts.—Mr. NEVILLE CHAMBERLAIN replied: It is estimated that 768,047 houses have been completed in England and Wales since the Armistice, 479,842 with State assistance under the housing Acts, and 288,205 without such assistance. Of the latter, 207,700 houses are of a rateable value not exceeding £26 in the provinces or £35 in the Metropolitan Police District. Approximately 209,500 houses have been erected in rural districts during the same period—117,000 under the housing Acts, and 92,500 without subsidy. Of the latter, some 79,200 are of a rateable value not exceeding £26 (£30 in the Metropolitan Police District).

Vacancy on the General Medical Council.

Viscount SANDON asked the Vice-Chamberlain of the Household, as representing the Lord President of the Council, whether the Lord President would select a non-professional member to fill the vacancy in the General Medical Council in January; and when his name would be announced.—Major HENNESSY replied: As I informed my noble friend in June last, it is not possible to say in advance what action the Lord President may see fit to take when the occasion arises for filling the vacancy now in question.

Viscount SANDON: Then I take it that there is no Parliamentary control in this matter at all.

No answer was given.

Reduction in Housing Subsidies.

On a motion by Mr. NEVILLE CHAMBERLAIN (Minister of Health) "That the draft of the Order proposed to be made by the Minister of Health and the Scottish Board of Health, with the approval of the Treasury under Section 5 of the Housing (Financial Provisions) Act, 1924 (presented Nov. 25th, 1926), be approved," Dr. HADEN GUEST said while there was a certain amount of theoretical justification at the present time for any effort to reduce national expenditure, the question was whether this proposal was either an economical or a proper way of doing so. He should like proof of the assertion of the Minister of Health that costs of building were likely to come down. But the real reason against reducing the subsidy was this. The subsidy was intended not to meet a normal condition of things, but a condition of things which 20 years before the war was already abnormal, and which during and since the war, with a slight amelioration lately, had grown steadily worse. They had not overtaken the arrears in normal housing. So far as he was aware they had not yet begun to touch the really serious slum question. How, then, was it possible to say that a subsidy which was imposed for dealing with an emergency should be removed before any reasonable being could assert that that emergency was abating? The reduction was altogether too general. Areas differed in the urgency of their demands. If the subsidy was to be reduced at all—and he did not admit that it was logical, desirable, or defensible to do so—then it should only be reduced in particular areas where it could be shown that the problem was being dealt with adequately. He would urge the Minister not to reduce the subsidy in rural areas. The Minister was very well informed as to what the housing conditions were by an army of medical men and public health officers all over the country, who sent him reports couched in language which if it were used by him (Dr. Haden Guest) would probably be stigmatised in the Press as Bolshevist propaganda. Let him refer in particular to the report of the medical officer of health for Birmingham. He had just been down in his own constituency (Southwark), and he had been besieged by people wanting rooms, and to know how they could get out of their overcrowded condi-

tions. He confessed that it was absolutely necessary to abstract oneself from the heart-rending vision of suffering and misery in order to be able to contemplate this problem cogently and clearly, but that did not excuse the Minister of Health for taking a course which was going to make it much more difficult, especially in the poorest and hardest-hit areas, to get houses erected and to get the slum problem dealt with. If the Government really meant business, instead of closing up on the subsidy they would have gone on with the present subsidy arrangements and added to them a big programme of slum clearance.

Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) said the present Government was as anxious as any government to avoid any break in the continuity of house production which was proceeding at an unexampled rate and had been exceeded by no other country in the world. Of the 750,000 new houses completed in this country since the war, nearly half had been completed during the last two years. They desired to exceed, if possible, that fine record. There was, indeed, every indication in the housing figures which were now presented to them that during the next 12 months they would do even better, and that the 200,000 mark would be passed. It was a modest step and a modest reduction which they were making, and it was in the right direction. The main object was to reduce the cost of housing, and it was a very well-advised step to begin to end the vicious and destructive system of subsidy, which was as bad for the building trade as for any other industry.

The resolution approving the draft of the Order was carried by 181 votes to 111.

MONDAY, DEC. 6TH.

Housing (Rural Workers) Bill.

The Housing (Rural Workers) Bill was considered on Report, and read a third time.

Infantile Paralysis in Rutland.

Colonel GRETTON asked the Minister of Health if there had been any further outbreaks of infantile paralysis in the county of Rutland; if so, what was the date of the latest recorded case; and if he could say the length of the period which his department considered should elapse before danger of infection or contagion ceased in ordinary cases of this disease.—Sir KINGSLEY WOOD replied: No further cases of this disease have been notified in Rutland since the occurrence of two cases at Uppingham School during the week ended Nov. 13th. As regards the last part of the question, in the present state of knowledge of this disease it is the practice of my right hon. friend's Department to recommend the isolation of patients who have been attacked by it for a period of six weeks from the date of onset of the disease.

Opium Restrictions in India.

Mr. CECIL WILSON asked the Secretary of State for the Colonies whether, as a result of the Government of India's decision to reduce by 10 per cent. per annum the export of opium except for medical and scientific purposes, the imports into British dependencies in the Far East would be proportionately reduced; and whether he could give an assurance that opium for purposes of smoking would not be imported from other sources to compensate for the reduction in the imports from India.—Mr. AMERY replied: No, sir. No such reduction would in my opinion be practicable in present circumstances.

Vivisection in London Physiological Schools.

Sir ROBERT GOWER asked the Home Secretary the number of dogs which had been used for vivisectional experiments at physiological schools in the London Metropolitan area during the past 12 months.—Capt. HACKING replied: Since Jan. 1st of this year 823 dogs have been used for experimental purposes in premises within the London area which are registered under the Act. All but a very few of the animals were kept under complete anæsthesia during the whole of the time of the experiment, and were destroyed before recovering from the anæsthesia.

Sickness and Disablement Benefit in 1925.

Mr. DAVID GRENFELL asked the Minister of Health how many working days were lost through illness by contributors towards the national health insurance schemes, with the total amount of benefit paid in the year 1925.—Mr. NEVILLE CHAMBERLAIN replied: The total amount of sickness and disablement benefit paid in the year 1925 to contributors to the National Health Insurance schemes in England and Wales during periods of illness which rendered the contributors incapable of work, was approximately £13,849,000. Exact particulars are not available as to the number of working days for which sickness and disablement benefit were paid, but it is estimated that the total number of weeks of sickness represented by the above payment is upwards of 25,000,000. In making this estimate, account has to be taken of a number of uncertain factors, and the result can only be regarded as a rough approximation.

Medical and Surgical Treatment in Poor-law Institutions.

Major TASKER asked the Minister of Health whether he was aware that boards of guardians were advised that they had no power under the existing law to refuse the admission to Poor-law institutions for the purpose of medical or surgical treatment of persons who could afford to pay for the necessary treatment; and whether he would introduce legislation giving boards of guardians convenient powers to take, where necessary, legal steps to recover from the estates of the patients the whole or a suitable proportion of the cost of their treatment and maintenance both in cases in which the patient was in receipt of an old age pension or of sickness or disablement benefit under the National Health Insurance Acts and in cases in which the patient was not in receipt of any such moneys.—Mr. NEVILLE CHAMBERLAIN replied: It is the duty of a principal officer of a Poor-law institution to admit an applicant, without any order for relief, in any case of sudden or urgent necessity, but the guardians have powers in certain circumstances to recover the cost of relief. As regards health insurance benefits, it is an essential feature of the National Health Insurance Act, embodied in the original scheme of 1911, and repeated in subsequent enactments, that money payable by way of benefit shall not be diverted to Poor-law authorities or otherwise used to relieve local rates. The intention of the Act is that sickness benefit should primarily be devoted to the necessities of the individual and his family, and benefit is not assignable. As regards old age pensions, the relevant part of the Contributory Pensions Act re-enacts Section 3 (1) of the Old Age Pensions Act, 1919, which provides that a person shall be disqualified for receiving or continuing to receive a pension while he is an inmate of any workhouse or Poor-law institution—with a saving proviso which raises the disqualification for three months where recourse is had to a Poor-law institution only for the purpose of surgical or medical treatment. A suggestion that inmates of Poor-law institutions should not, as such, be disqualified for receiving old age pensions but that the pensions should be appropriated by the guardians was considered, but rejected by the Departmental Committee on whose recommendation Section 3 (1) of the Act of 1919 was based.

Public Health (Smoke Abatement) Bill.

This Bill was considered on Report, and an amendment to bring the chimneys of domestic dwelling-houses in London within its scope was negatived. Sir A. HOLBROOK moved to include private dwelling-houses in the clause which gives urban authorities power to require in new buildings the provision of such arrangements for heating and cooking as are calculated to prevent or reduce emission of smoke. —Mr. NEVILLE CHAMBERLAIN (Minister of Health) said that only a trifling number of houses could be affected by the amendment; he was not prepared to deny to house-holders the use of the open fire until there was a reasonably cheap and satisfactory alternative.—The amendment was rejected by a majority of 138. The operation of the Bill was postponed from Jan. 1st to July 1st.

TUESDAY, DEC. 7TH.

Saltash Pensions Hospital.

Mr. BRIANT asked the Minister of Pensions how many patients at the Saltash Pensions Hospital had discharged themselves during the last 12 months; and if he had made inquiry into the food and general condition of that institution. —Lieut.-Colonel STANLEY (Parliamentary Secretary to the Ministry of Pensions) replied: During the period referred to 63 men discharged themselves against medical advice from Saltash, after an average period of stay in the institution of close upon six months. I understand that while in several of these cases the men must be regarded as practically irresponsible for their actions, most of the men discharged themselves for domestic reasons. The hospital is regularly visited by medical inspectors of the Ministry, and my right hon. friend is satisfied that the feeding and general arrangements are satisfactory.

Specialist Medical Service for Insured Persons.

Mr. HORE-BELISHA asked the Minister of Health when it was proposed to put into operation the recommendation recently made by the Royal Commission on National Health Insurance that the scope of the benefit should be extended to include a consultant and specialist medical service and that the necessary funds for that purpose should be obtained by a partial pooling of future surpluses of approved societies. —Major HENNESSY replied: My right hon. friend is not at present in a position to say what action will be taken with regard to the recommendation to which the hon. Member refers.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.
MONDAY, Dec. 13th.—5.30 P.M., WAR. Cinematograph Demonstration: Lieut.-Colonel E. M. Cowell: Thomas's Splint Drill. Paper: Surgeon-Comdr. H. E. R. Stephens, R.N.: Abdominal Hernia in the Royal Navy.
TUESDAY.—5.30 P.M., GENERAL MEETING OF FELLOWS and Ballot for the Election to the Fellowship. 5 P.M., THERAPEUTICS AND PHARMACOLOGY. Papers: Dr. Curtis and Dr. Sampson Wright: On the Action of Lobeline. Dr. R. Hilton: On a Comparison of Some Methods of Administration of Oxygen. 8.30 P.M., PSYCHIATRY. Presidential Address: Dr. W. Aldren Turner: Some Observations Upon Epilepsy.
WEDNESDAY.—5 P.M., HISTORY OF MEDICINE. Papers: Dr. A. Davies: A Montpellier Diploma. Mr. C. J. S. Thompson: A Historic Case of Surgical Instruments. (The case of instruments presented to the Royal College of Physicians in 1652 will be exhibited by kind permission of the President and Council of the College.) Prof. Siddigi (Madras): Medical Case-notes from Arabic Literature (communicated by Dr. Singer). Dr. Charles Singer: An Example of the Egyptian God Bes exhibiting Symptoms of Spina Bifida.
THURSDAY.—5 P.M., DERMATOLOGY. (Cases at 4 P.M.) Cases: Dr. Parkes Weber: (1) Very Severe Prurigo of Besnier in an Adult. Dr. E. G. Ffrench: (2) Lupus Erythematosus Affecting Fingers Only; (3) Lupus Verrucosus. Other cases will be shown.
FRIDAY.—8 P.M., ELECTRO-THERAPEUTICS and SURGERY. Attention is drawn to the alteration in the time of this meeting. Special Discussion on Diathermy. Speakers: Dr. E. P. Cumberbatch (for the Section of Electro-Therapeutics); Mr. F. J. Steward (for the Section of Surgery); Mr. Gwynne Williams and others will also take part in the discussion.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.
MONDAY, Dec. 13th.—8.30 P.M., Discussion on Recent Advances in the Ætiology, Diagnosis, Prophylaxis, and Treatment of the Exanthemata, to be introduced by Dr. J. D. Rolleston, followed by Dr. R. A. O'Brien.

ST. JOHN'S HOSPITAL DERMATOLOGICAL SOCIETY.
WEDNESDAY, Dec. 15th.—4.15 P.M., at St. John's Hospital, Leicester-square: Clinical cases will be shown and a paper will be read by Dr. P. J. Edmunds on Skin Affections following Vaccination.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.
WEDNESDAY, Dec. 15th.—1.45 P.M., Dr. Norman Mackeith: Examination of Accessory Sinuses.
FRIDAY.—1.45 P.M., Mr. J. D. McLaggan: Examination of the Nose. 4 P.M., Mr. Harold Kisch: The Operative Treatment of Nasal Sinus Suppuration.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, Dec. 13th, to SATURDAY, Dec. 18th.—FELLOWSHIP OF MEDICINE. Special Lecture at the Medical Society, 11, Chandos-street, Cavendish-square. Thurs., Dec. 16th, at 5 P.M., Mr. Ernest Clarke: Emergencies in Ophthalmic Practice. Free to all members of the medical profession.—INFANTS HOSPITAL, Vincent-square, S.W. Special Course on Diseases of Infants. Every afternoon from 2 P.M. Special Lectures and Demonstrations.—WEST END HOSPITAL FOR NERVOUS DISEASES, 73, Welbeck-street, W. Special Lecture-demonstrations upon Selected Cases at 5 P.M. Further information from the Secretary of the Fellowship of Medicine.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.
MONDAY, Dec. 13th.—11 A.M., Mr. Tyrrell Gray: Surgical Wards. 12 noon, Mr. Simmonds: Demonstration of Fractures. 2 P.M., Dr. Trevor Davies: Gynæcological Department.
TUESDAY.—11 A.M., Mr. Endean: Venereal Disease Demonstration. 12 noon, Dr. Burrell: Chest Cases. 2 P.M., Mr. Sinclair: Surgical Out-patients.
WEDNESDAY.—10.30 A.M., Dr. Burnford: Medical Wards. 2 P.M., Dr. Owen: Medical Out-patients. 2 P.M., Mr. Tyrrell Gray: Operations.
THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Department. 2 P.M., Dr. Scott Pinchin: Medical Out-patients. 3.30 P.M., Sir Henry Simson: Gynæcological Wards.
FRIDAY.—10 A.M., Dr. Dowling: Skin Department. 11 A.M., Dr. Pritchard: Modern Methods in Medicine. 2 P.M., Mr. Addison: Operations.
SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy Department. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.
Daily, 10 A.M. to 5 P.M., Operations, Medical, Surgical, and Special Out-patient Departments. Saturdays, 10 A.M. to 1 P.M.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
MONDAY, Dec. 13th.—10 A.M., Surgical Clinic. 2 P.M., Medical Cases in the Wards. 2.30 P.M. to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.
TUESDAY.—2.30 P.M. to 5 P.M., Medical, Surgical, Throat, Nose, and Ear Clinics. Operations.
WEDNESDAY.—2.30 P.M. to 5 P.M., Medical, Skin, and Eye Clinics. Operations.
THURSDAY.—11.30 A.M., Dental Clinic. 2.30 P.M. to 5 P.M., Medical, Surgical, and Ear, Nose, and Throat Clinics. Operations.
FRIDAY.—10.30 A.M., Throat, Nose, and Ear Clinics. 2.30 P.M. to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.
On Tuesday, Dec. 14th, and Friday, Dec. 17th, at 2.30 P.M., there will be special demonstrations of Ear, Nose, and Throat Cases and Surgical Cases, by Mr. W. Ibbotson and Mr. E. Gillespie respectively.

THE LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.
TUESDAY, Dec. 14th.—5 P.M., Dr. S. E. Dore: Erythemato-Squamous Eruptions.
THURSDAY.—6 P.M., Dr. J. T. Ingram: Pathology Demonstration.

POST-GRADUATE HOSTEL, Imperial Hotel, Russell-square, W.C.
TUESDAY, Dec. 14th.—9 P.M., Prof. C. A. Lovatt Evans: Capillary Circulation.
THURSDAY.—Mr. A. E. Mortimer Woolf: Pain.
FRIDAY.—Dr. T. Wilson Parry: The Differential Diagnosis of the Various Kinds of Holes Discovered in the Skulls of Prehistoric Man.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.
TUESDAY, Dec. 14th.—4.15 P.M., Mr. J. Howson Ray: Spinal Caries with Paraplegia.
FRIDAY.—4.15 P.M., Dr. E. F. Hill: Blood Changes During Anæsthesia.

ST. MARGARET'S HOSPITAL FOR WOMEN, Acomb-street, Whitworth Park, Manchester.
WEDNESDAY, Dec. 15th.—4.15 P.M., Mr. A. C. Magian: Ovarian Grafting for the Cure of Sterility.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.
FRIDAY, Dec. 17th.—3.30 P.M., at the Royal Infirmary: Mr. Finch: Strictures, Innocent and Malignant.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, St. Andrews.
TUESDAY, Dec. 14th.—4 P.M., Prof. Murray Lyon: Methods of Influencing the Blood Pressure. Discussion to be opened by Dr. W. F. Mair.

CHADWICK PUBLIC LECTURES.
MONDAY, Dec. 13th.—8 P.M. (at the Royal Sanitary Institute, 90, Buckingham Palace-road), Mr. W. A. Robson, Ph.D.: Legal Conceptions of Public Health.

Appointments.

JEFFERSON, G., M.B., M.S. Lond., F.R.C.S., has been appointed to the newly-created post of Honorary Neurological Surgeon at the Royal Infirmary, Manchester.
MURCHISON, K. D., M.B., Ch.B. Glasg., Certifying Surgeon under the Factory and Workshop Acts for the Shaw District of the County of Lancaster.
SMITH, NORA F., M.B., B.S. Lond., D.P.H., to take charge of the Maternity and Child Welfare Department of the City of Manchester.
North Middlesex Hospital: RAMSAY, FREDA, M.D., B.S. Durh., D.P.H., D.O.M.S., Ophthalmic Surgeon: FIGDOR, P., M.B., Ch.B. Glasg., Medical Electrician and Actinotherapist.

Vacancies.

For further information refer to the advertisement columns.

All Saints' Hospital for Genito-Urinary Diseases, Vauxhall Bridge-road, S.W.—Res. Sen. H.S. Also Non.-Res. Jun. H.S. At rate of £200 and £100 respectively.
Bethnal Green Borough Council.—Consulting Obstetricians. £5 5*s.* per case.
Brighton, New Sussex Hospital for Women and Children.—Hon. Asst. P. Also Hon. Clin. Asst.
Brighton, Sussex, Maternity and Women's Hospital.—Second Hon. Obstet. Phys.
Cairo University.—Prof. of Pathology. £E.2000. Also Prof. of Bacteriology. £E.1500.
Cancer Hospital, Fulham-road, S.W.—Pathologist. £1000.
Capetown, City of—Med. Supt. of Hospitals. £800.
Cardiff City Mental Hospital, Whitchurch.—Res. Clin. Asst. 50 guineas for six months.
Dreadnought Hospital, Greenwich.—H.P. and H.S. Each at rate of £110.
East London Hospital for Children and Dispensary for Women, Shadwell, E.—H.S. At rate of £125.
Glasgow, Consumption Sanatoria of Scotland, Bridge of Weir.—Asst. Res. M.O. £200.

Hammersmith Infant Welfare Centre.—M.O.
Hampshire County Council.—Dental S. £500.
Hospital for Sick Children, Great Ormond-street, W.C.—Surg., Phys. to Out-patients. Anæsthetist. £15 15*s.*
Ipswich, East Suffolk and Ipswich Hospital.—H.S. and Cas. O. Each at rate of £100.
Lambeth Parish Hospital.—Two Jun. Asst. M.O.'s. £200 each.
Maidstone, Kent County Mental Hospital.—Asst. M.O. £300.
Maidstone, West Kent General Hospital.—H.S. £220.
Manchester, Ancoats Hospital.—H.S. At rate of £100.
Miller General Hospital for South-East London, Greenwich-road, S.E.—Res. Cas. O. £150. Also H.S. £125.
Newcastle-upon-Tyne, Princess Mary Maternity Hospital.—Asst. Res. M.O. At rate of £40.
Oldham Royal Infirmary.—H.S. At rate of £200.
Oxford, Radcliffe Infirmary and County Hospital.—H.S. and Obstet. H.P. Each at rate of £120.
Prince of Wales's General Hospital, Tottenham, N.—Hon. Asst. S., Physio-Therapeutist, and Hon Asst. P. or S. to X Ray Dept. Also H.S.
Rochdale Infirmary and Dispensary.—Jun. H.S. £200.
Royal Army Medical Corps.—Commissions.
Royal Free Hospital, Gray's Inn-road, W.C.—Orthopædic Surg.
Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—H.P. At rate of £100.
St. Mary's Hospital, Institute of Pathology and Research.—Research Studentship. At rate of £200.
St. Mary's Hospital, W.—Med. Registrar. £200.
St. Peter's Hospital for Stone, &c., Henrietta-street, Covent Garden, W.C.—Clin. Assts.
Salford Royal Hospital.—Res. Surg. O. £200. Two H.S.'s, H.P., and Cas. H.S. Each at rate of £125.
Sheffield, Jessop Hospital for Women.—Asst. H.S. At rate of £100
Sheffield Royal Infirmary.—H.S. At rate of £80.
Stockport Infirmary.—H.S. £175.
Sutton, Surrey, Downs Hospital for Children.—Ass. M.O. £550.
Wrexham and East Denbighshire War Memorial Hospital.—Two Res. H.S.'s. Each at rate of £100.

The Chief Inspector of Factories announces vacant appointments for Certifying Factory Surgeons at Lymm (Cheshire) and Driffield (Yorks).

Births, Marriages, and Deaths.

MARRIAGES.

CORKHILL—JONES.—On Nov. 26th, at St. James's Church, Birkdale, Joseph G. G. Corkhill, M.D., to Julia F. Wheatley Jones, of Ellerslie, Birkdale.

MORGAN—MACDONALD.—On Dec. 1st, at the Marylebone Presbyterian Church, Oswald Gayer Morgan, M.Ch., F.R.C.S., to Jessie Campbell MacDonald, younger daughter of Colin MacDonald and Mrs. MacDonald, of Abbey-road, St. John's Wood, N.W.

DEATHS.

DATE.—On Dec. 4th, suddenly, Margaret, the beloved and loving wife of William Horton Date, of 3, Homefield-place, Exeter.

HEARNDEN.—On Dec. 2nd, suddenly, at Cavendish Lodge, Cavendish-road, Sutton, Surrey, Ernest Morgan Hearnden, M.R.C.S. Eng., L.R.C.P.

HYDE.—On Nov. 29th, suddenly, at Newport, Mon, John Wilkinson Davis Hyde, M.R.C.S., L.R.C.P., Tuberculosis Physician, Monmouthshire, under King Edward VII. Welsh National Memorial Association, aged 33.

WHITELAW.—On Dec. 4th, suddenly, at St. George's-road, Golders Green, Dr. William Whitelaw, aged 77.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

HOSPITALS IN NORTHERN AMERICA.

AN ADDRESS BEFORE THE ULSTER MEDICAL SOCIETY.

Prof. C. G. LOWRY read a paper entitled Notes on Hospitals and Hospital Administration in Canada and the United States at a meeting of the Ulster Medical Society held on Dec. 2nd with Dr. M. J. Nolan, the President, in the chair. After paying warm tribute to the kindness and hospitality he had everywhere received during a recent American visit, Prof. Lowry spoke of some differences in organisation and in technique between the trans-Atlantic hospitals and our own. He found in the entrance hall of many hospitals desks marked "Information" on one side and "Hostess" on the other side. At the former there was an official whose function it is to receive visitors to the hospital, to answer inquiries from friends of patients, and to direct visitors where certain people could be found. At the other desk an official interviews the friends of intending patients and deals with applicants for private accommodation in the hospital. The new hospitals in Canada and the States were constructed of four or five stories, and much use was made of electric lifts. In some cases the kitchen and stores were upon the fifth floor, each floor having a separate lift. Food distribution was effected by what might be called a "field kitchen," wheeled in turn to each patient's bed, and this plan seemed to work well, and to save labour to the nurses. Noise was mitigated by thick rubber flooring. No bells were allowed. In some hospitals each bed had a bell-push which, when pressed, sounds a faint buzzer at the desk of the nurse in charge, and at the same time a small numbered disc on her desk is illuminated, corresponding with the number of the bed. Much ingenuity was evident in labour-saving devices.

In the great majority of hospitals provision was made both for public and for paying patients; in some cases there was a special wing, in others a separate pavilion. The private pavilions had their own separate X ray installation, sometimes separate laboratories, and the operating theatres were on the most approved plan. The cost of private accommodation was high, and it was an index to the prosperity of the countries that the high figures were willingly paid. Substantial profits accrued from the pay wards. Prof. Lowry thought that if there were equal numbers of pay and public patients a hospital might be made almost self-supporting. The ratio of private to public patients was usually about 1 to 2. In some cases the municipality paid 6*s.* per diem for indigent patients. All patients contributed to the hospital.

In the modern maternity hospitals there were about five delivery rooms to every 100 patients, with two operating theatres. Some of these hospitals had well-isolated septic departments, a nursery for children of septic mothers, and an isolation nursery for babies suffering from any infection. Adjoining the delivery rooms accommodation was provided for the practitioner to rest if his case was delayed. In several hospitals a small single-bed ward connected with the main wards was used for a dying patient, thus saving much nervous strain to the other patients. Sitting-rooms for the relatives of patients were provided in some places.

Nursing Conditions.

Nursing is maintained at a high level, and the social status and educational equipment of the nurses are higher than at home. Many nurses are graduates in arts or science. The remuneration is good, ranging from about 26*s.* to 32*s.* per diem. The nurses' quarters are often admirable. The course of training is on much the same lines as at home. In many of the hospitals there is a "metabolic" kitchen, where diets for special cases, such as diabetics and nephritics, are specially prepared under a diet nurse. Some of these cases after convalescence are detained in hospital for several weeks and undergo a tuition course with lectures and demonstrations, preparatory to their discharge from hospital.

The arrangements for the welfare of babies in the maternity hospitals were good, one or two nurseries being available on each floor. At feeding time the babies were wheeled on trolleys to the wards and distributed to their mothers, and, when fed, were promptly wheeled back. Any mother suffering from a catarrhal affection had to wear a mask when nursing her child, and no visitors were allowed in the nurseries. In one maternity hospital each child had a separate bath, which was sterilised daily, a separate sterile towel, and a separate washcloth, and the nursery floor was washed daily with lysol soap. The identification of a baby was provided for by necklets of beads stamped with the letters of its name. Much importance was attached to the maintenance of an even temperature in the nurseries, since it was found that, if the temperature of the nursery fell 5° in 24 hours, the babies lost weight.

The regulations in regard to visitors both in maternity and in general hospitals were much more stringent than in the home countries. Children were not allowed to visit maternity hospitals under any circumstances. Even in the private pavilions only two visitors were allowed to a patient, and in the public wards of the maternity hospitals, as a rule, only one visitor was permitted. In one hospital patients who had undergone abdominal section were allowed no visitors until after the fourth day, except one relative for a few minutes.

As regards anæsthesia, the routine was gas and oxygen, followed by ether or ethylene gas. Chloroform was never employed. Radium was generally preferred to operation in primary carcinoma of the cervix uteri. The results were good. Protein injections were largely used in gynæcological infections. Blood transfusions were a routine measure in all poor operative risks. Blood pressure observations are more frequently studied than in some other countries. Rectal examinations with the gloved finger were the rule, vaginal examinations being reduced to a minimum.

The arrangements for teaching are good. In some cases accommodation with residence was provided for students in the hospitals. Medical schools limited the number of students according to their clinical material, and overcrowding was prohibited.

DANGERS OF THE BARBER'S CHAIR.

A RECENT essay by Dr. K. G. Colquhoun[1] on Some Dangers of the Barber's Chair, is worthy of the attention of all the barber's clients. It is not only in Australia that many hairdressers ply their trade to the danger of the public, and in London, at any rate, it is exceptional to find a shop where the arrangements are such that the well-informed can feel themselves fully guarded against infection. A great many hairdressing establishments would find no customers were it not that the population at large is not fastidious and busy people are almost compelled to use the services of those they find at hand.

It is in the public interest that barbers and their assistants should be compelled to study those diseases of the scalp, beard, and nails which experience has shown to be due to microbic infection. If the germs of a disease are present on the scalp or face the barber's implements are at least as effective as the platinum loop for their conveyance and inoculation on a fresh and hitherto uncontaminated medium—the next scalp or face that presents itself. Whether a disease is thereby immediately or remotely contracted depends on a number of chances which it is difficult to estimate. The success or otherwise of inoculation is governed by the degree of resistance (acquired or inherited) of the individual, by measures taken to cleanse the contaminated part, by the virulence of the infecting organism, and by many other factors as well. By no means every purposive and scientific inoculation succeeds, and those who escape an accidental infection are admittedly in the majority. It cannot be denied, however, that from time to time there are definite cases of specific infection in which the conveying agent must have been the barber's instrument. Of these infections three, in virtue of their highly characteristic clinical and microscopic appearances, are particularly worthy of mention: impetigo (due to a virulent streptococcus), seborrhœa capitis, and tinea in its various forms and situations.

Impetigo has a habit of occurring in local epidemics; one of these was a particularly obstinate outbreak of the disease last year in a London club, whose members had attended the same hairdresser. In this instance it was easy to trace the source of the infection and prevent fresh cases arising, but where the victims are not friends or acquaintances and are unaware of other cases, the difficulties of apportioning responsibility and eliminating the source of infection may well be insurmountable.

Seborrhœa of the scalp, being a condition in which the symptoms are chronic and not in the least dramatic, is apt for a long time to escape the observation of the untrained eye. It is known by various names—seborrhœa capitis (sicca or oleosa), pityriasis, dandruff, scurf, and in certain more acute phases, eczema of the scalp. Many dermatologists regard it as the most potent cause of baldness in the male. Whatever may be said for the pre-existence of a suitable nidus or terrain, it is the general opinion that the most important part in the production of this condition is played by micro-organisms, and if these premises are correct, a moment's reflection will convince all but the most sceptical that the promiscuous use of a hair brush must be a very potent source of seborrhœic infection, and should be scrupulously avoided.

The third and more demonstrable danger of the communal brush is ringworm of the hairy scalp. This danger, it is true, exists only for children under the age of 16, but is nevertheless, a very real one, especially in schools, and assuredly it explains the frequency with which batches or groups of cases are detected at the same time. It is more than probable that no ordinary means of disinfection would succeed in sterilising a brush that had once been used on a case of tinea tonsurans, for the resistance to all the usual disinfectants of the causal mycelium is notorious, even when it is lying outside the hair shaft.

It is probable that the above diseases are conveyed fairly frequently from head to head, and the possibility of this conveyance could very easily be reduced by (1) the client's insistence on the use of none but his own apparatus; (2) certain simple tonsorial regulations, possibly formulated and enforced by the public health authorities. It must not be forgotten that the shaving brush is also a potential danger although, theoretically at least, not to the same extent as the hair brush, because of its more frequent and more drastic contact with hot water and soap. Shaving brushes from certain countries have, of course, been the proven cause of occasional outbreaks of anthrax in England. Razors, owing to their conformation and structure, and to their being frequently dipped in hot water, are relatively harmless implements of infection, although the blunt and clumsily-handled variety can do a good deal to promote the local condition termed barbers' rash, or sycosis, by the production of minute abrasions of the skin surface. Combs and clippers, too, have been pilloried on occasions, and in some cases the use of clippers may be responsible for boils of the neck.

It is opportune, perhaps, to draw attention to the risks which may be run in ill-conducted manicure and chiropody parlours. Ringworm of the nails is rare, but cases have been traced to the use of a manicure set by several persons, whilst the possibility of conveying whitlow infections, and even syphilis, by manicure will be apparent to any medical reader.

Conditions of hairdressing have certainly improved during the past few years, and antiseptics are freely used, though not always intelligently; but there is much room for further observance of the detail of asepsis in these establishments in view of the great amount of harm which barbers may inflict on the community if they are uninstructed and uncontrolled.

FARMING AND VITAMINS.

A PAPER by Colonel R. McCarrison (*Indian Jour. Med. Res.*, 1926, xiv., 351) shows that the manurial history of cultivated land may have an influence on the vitamin content of cereals grown on it. By appropriate feeding experiments on pigeons and rats he shows that millet grown on soil manured with farmyard manure yields a grain of higher nutritive value than when it is cultivated on the same soil manured with a complete mineral artificial manure; soil which has been continuously cropped for many years without being manured at all produced grain of very low nutritive value. The same differences between natural and artificial manures were found for wheat, though this grain had a fairly high value even when no manure had been used. Manuring, therefore, affects quality as well as quantity. No artificial manure has, we believe, been found which will over long periods give yields of wheat equal to those obtained with dung: quantitatively the empirical wisdom of pre-chemical farming is still justified, and these results suggest the possibility that the early agriculturists, growing cereals for their own as much as for other's use, had found its qualitative excellence too. In any case, it is clear that those whom lusty viscera enable to advocate wholemeal bread by personal example will have to consider the source of their grain: "dung-fed bread" may follow "grass-fed milk."

LIGHT AND TYPESETTING.

RECENT investigation into the adverse effect of artificial illumination, as compared with daylight, upon physical efficiency, has been confined to the textile industries. But in the printing trade work is largely done after daylight has failed, or in places where artificial light is needed during daylight hours, and exact information[1] as to the amount of illumination necessary for typesetting by hand is very welcome. Before this investigation was made no knowledge existed as to the loss of efficiency, both in quantity and quality of output, through work being carried on under insufficient light. The standard of output chosen for the test was that attained during a daylight illumination of not less than 50 ft.-candles and sometimes as high as 495, the mean being 160 ft.-candles. The sources of light throughout were so placed as to avoid glare. Gas-filled lamps were used, and care was taken to arrange their position and height so that the angle of "cut off" was greater than 30°. The compositors then worked under artificial light of varying power. With an illumination of

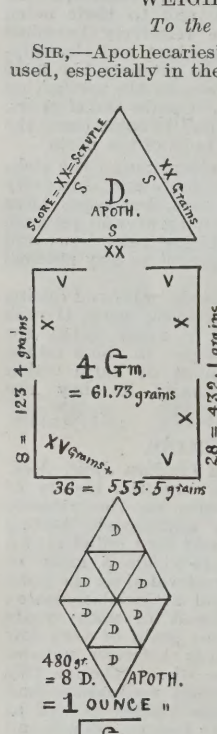
[1] The Relation between Illumination and Efficiency in Fine Work (Typesetting by Hand). Joint Report of Industrial Fatigue Research Board and Illumination Research Committee. Pp. 12. London: H.M. Stationery Office. 1926. 6*d*.

less than 2 ft.-candles (by no means an exaggerated dimness in ordinary factory life), a quarter of the possible output was lost, mistakes were doubled, and fatigue was materially increased. When the illumination reached 7 ft.-candles—a value higher than that of present general practice—over 10 per cent. of possible output was still lost, and a high percentage of errors occurred; but at this value no fatigue effect was manifest. This is an interesting point, for it suggests that the standard of conditions requisite for health may be considerably below what is economically advantageous from the viewpoint of production. Not until the artificial illumination was raised to about 20-ft. candles did the amount and quality of output reach that of the daylight standard. The provision of such higher degrees of illumination is largely a question of expense, which the results of this investigation show to be worthy of consideration.

WEIGHTS AND MEASURES.

To the Editor of THE LANCET.

SIR,—Apothecaries' weights and measures are still largely used, especially in the United States of America, for, as you said in a review of the "Dispensatory" (THE LANCET, Nov. 13th, p. 1015), practically all American prescriptions are written in this measure. Since the apothecaries' and the metric units are likely to be used side by side for some time, at any rate, some mnemonical aid to memory should be useful. The accompanying diagram may help to visualise the relationship between the two systems. "Drachm" and "gramme," being both of Greek etymology, are represented in the diagram by Greek letters, the triangle standing for delta, the square for four gammas. The D also stands for drachm and the G for gramme. The triangle is to be accepted as equal in value or area to the square, each side of the triangle as being a score of grains or one Scruple (Score and Scruple have the same initial letter), and each quarter of the square as a gamma or one gramme. The long arm of the gamma equals X grains and the short arm V, or XV together. The various relationships between drachm, gramme, and grains can then be seen at a glance or worked out on paper by the ordinary rules of arithmetic. The peculiar significance and sequence also of the additional figures supplied for grammes and grains—namely, 8, 28, and 36 equalling grains 123·4 and 432·1 and 555·5 will not be missed. When it is remembered, moreover, that an English sovereign weighs 123·274 grains and is obviously very near indeed to 8 grammes, or 2 drachms, then that weight can be at once visualised and the 28 grammes is only about 5½ grains under the weight of three pennies, which weigh one ounce avoirdupois (28·35 grammes). Again, as an example, half the triangle—that is, half a drachm (one of the series usually supplied by scale and weight manufacturers), is seen to be equal to half the square—that is, 2 grammes, or practically 30 grains. Apart from all the details, the fundamental thing is to visualise the delta triangle and the "square" of four gammas. The lozenge, or diamond, shows 8 drachms as equal to one ounce apoth. or troy, or 31·1 grammes.



I am, Sir, yours faithfully,

Dec. 1st, 1926. W.

PINK LUSTRE POTTERY.[1]

Dr. Atwood Thorne has written an interesting little monograph on the results of cultivating a taste for lustre earthenwares. He started his collection in pure chance by the purchase at King's Lynn of a teapot, with a cracked lid, "which reminded him of tea at his grandmother's house." It had upon it as decoration a cottage, trees, stables, a fence, and a conventional design of blobs, and he learned that his purchase was a specimen of a known class of pink lustre pottery which he calls the "cottage style." Complete sets he afterwards found difficult to pick up, but one of the excellent illustrations shows what should be looked for. The illustrations also show varieties of cup, saucer, basin, and jug, some of the last having upon them sporting scenes, while many of the receptacles for beer and cider bear elaborate floral or historic designs. Apparently a large number of the jugs and basins were manufactured for sailors, who affected them as presents to their sweethearts and wives, hence frequent embellishment with ships and compasses, and the many transfers to the pottery of sentimental verses. Dr. Thorne's book will be of use to those who have collected and may induce others to follow their example, when, however, they may not always meet such obliging purveyors as those whose assistance Dr. Thorne acknowledges handsomely.

[1] Pink Lustre Pottery. By Atwood Thorne, M.B. London: B. T. Batsford. 1926. 10*s.* 6*d.*

A MEMORY GOING BACK TO THE AGE OF SIX MONTHS.

THE child of 2 or 3 has an excellent memory, as many a parent will truthfully declare, but we rarely consider the problem of our adult loss of memory for these early years. Most of the events of the first few years of life are forgotten, although it is then that character traits and modes of emotional reaction are largely determined, and it is one of the claims of psycho-analysis that some at least of the infantile memories can be restored. Sometimes, as in the classical case of claustrophobia described by W. H. R. Rivers, the reality of the event concerned has been independently verified. But the memory of Rivers's patient was of a boyhood event, and there is a notable gap between it and those earlier memories, going back to the beginning of the second year, which psycho-analysis is said to reveal. In the *Internationale Zeitschrift für Psychoanalyse* (1926, Bd. xii., Heft 1), Mr. E. Pickworth Farrow, M.A., D.Sc., describes the recovery, by a process of self-analysis, of a memory in which he recalls not only his own actions, but his emotions and intentions in a family episode at the age of six months. In this case the memory was obviously not suggested by an analyst, but to the objection that it may be a phantasy, the writer's only reply is an appeal to personal experience in distinguishing between phantasy and actual memory. Psychology can offer only speculations as to the time of appearance of the consciousness of self, upon which depends not only the memory described by Dr. Farrow, but—what is really more important—the possibility of recognising at the time his own feelings and desires. There is, however, no intrinsic impossibility in the history and the newness and strangeness of the idea that so early a memory can persist in the unconscious must not prevent us from recognising the importance of such observations.

BRIGHTON GUARDIANS AND A NURSES' HOME.

BY 18 votes to 17 the Brighton Guardians have decided to build a nurses' home for the staff of the Poor-law Infirmary at a cost of £35,000. The matter had been before them for a long time, their previous decision being in favour of what the Ministry of Health described as a poor, inadequate, and makeshift scheme (THE LANCET, 1926, ii., 807). After the Ministry had declined to sanction their plan for the conversion of existing accommodation at a cost of £1150, the guardians appointed a special committee, and this unanimously reported that lack of accommodation caused the present difficulty in retaining a competent and contented nursing staff.

DONATIONS AND BEQUESTS.—The late Mr. George Paterson Walker, of Heatherwood, Putney Heath, S.W., left by will £2000 to Kilmarnock Infirmary.—By the will of Captain Athelstane Robert Pryce, late 18th Hussars, J.P., D.L., of Cyfronydd, Welshpool, the testator left £1000 each to the Royal Salop Infirmary and the Eye, Ear, and Throat Hospital for Shropshire and Wales.—The Royal National Orthopædic Hospital, Great Portland-street, W., has received a legacy of £2000 duty free from the late Miss Dora Clarita Abisdid.—Mr. Arthur Humpston, of Woking, formerly of Derby, bequeathed £2025 to the Royal Derby Infirmary to endow two beds in memory of his son, Arthur Robert, who was killed in Flanders in 1917, and after his wife's death £300 each to the Derbyshire Hospital for Sick Children, the Royal Institution for the Deaf and Dumb Derby, and the Railway Servants' Orphanage, and £7000 to the Royal Infirmary, Derby, to endow beds in memory of himself and his wife.—Mr. Bernhard Barron, of Hove, Sussex, has given £25,000 to hospitals and other philanthropic institutions in celebration of his seventy-sixth birthday.—The late Miss Jessie Ann Thomson, of Carlton-place, Aberdeen, left by will, among other bequests, £1000 each to Aberdeen Royal Infirmary and Aberdeen Royal Hospital for Sick Children; £500 to Morningfield Hospital and a similar sum to the Indigent Lunatic Fund Aberdeen.

Impressions OF THYROID SURGERY IN AMERICA.

BY W. SAMPSON HANDLEY, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO THE MIDDLESEX HOSPITAL; HON. FELLOW OF THE AMERICAN COLLEGE OF SURGEONS.

THE United States was described to me by one of its citizens as the most magnificent piece of real estate on the face of the globe. If Canada be included as part of the "lot," the description is certainly accurate. Nevertheless this rich continent seems to be short, at any rate in certain portions of its extent, of one thing besides rubber—namely, iodine, that essential element of vital chemistry. I was told of a certain farm in a fertile district of Western Canada where the farmer was threatened with ruin on account of the infertility of his stock. The importation of fresh blood failed to overcome the difficulty, but acting on expert advice the farmer mixed a minute amount of iodine or iodide with the drinking water. The remedy worked marvels, comparable to the peeled wands employed by Jacob for a similar object, and at the expenditure of about two dollars a year for iodide the curse of infertility has been completely exorcised.

The shortage of iodine is indicated, so far as concerns the human race, by the great frequency of goitre, especially of the exophthalmic variety, of thyroid adenomata, and of consequent hyperthyroidism in certain States. The maximum frequency seems to be attained on the Pacific slope, and a practitioner from this region told me that between 50 and 60 per cent. of his women patients suffered from hyperthyroidism. While in England hyperthyroidism in men is rare, it is quite common in the States. At Dr. George Crile's Cleveland Clinic thyroid operations —there often done by several stages—appear to be twice as common as all other operations together, no doubt because of the reputation Dr. Crile has attained in this field of surgery. At the Mayo Clinic, too, as judged by one day's list, about one operation in six is a thyroid operation.

HEAVY INCIDENCE OF HYPERTHYROIDISM IN AMERICA.

It would be interesting to speculate as to the reason for the heavy incidence of hyperthyroidism in America. Is it due merely to a continental shortage of iodine, or is it due mainly to the strain of the strenuous American life? That Americans believe iodine-starvation is an essential factor is shown by the wide prevalence of the custom of giving iodine tablets as a routine to growing children. I believe one tablet a week, containing about $\frac{1}{4}$ gr. of iodine, is regarded as a reasonable dose, or the iodine may be given as an iodised table salt. It must be remembered that few American children can enjoy the yearly visit to the sea, and the generous provision of salt-water fish, which provide iodine for the growing English child. It would seem that the intellectual stress which often appears to produce exophthalmic goitre in the clever and ambitious American college girl might usually be harmless in a body adequately stocked with iodine.

It would be going too far to suggest that the restless activity which characterises America indicates a national basal metabolism raised by iodine shortage. It is natural that a great nation in the first flush of its national virility should be restless and eager, and there is no need to find a pathological explanation of these phenomena. Nevertheless the speculation is interesting.

It will be evident that the medical profession in America has enjoyed excellent opportunities for the study of hyperthyroidism, and it has used them very effectively. Particularly it has ended the controversy which has raged for years as to the advisability of giving iodine in hyperthyroid conditions. In Europe one school, headed by Kocher, considered that the administration of iodine in such conditions was a dangerous and indefensible practice, likely at the best to do no good, and at the worst to cause complete breakdown. Other authorities considered iodine a valuable remedy.

THE RÔLE OF IODINE IN THE TREATMENT OF HYPERTHYROIDISM.

A school of metabolists in America, headed by Plummer, of the Mayo Clinic, has reconciled these opposing views. They have shown that iodine is no permanent remedy for hyperthyroidism, but on the other hand that it has a powerful if temporary controlling influence on the symptoms for a period of several months when used in appropriate and moderate doses. The administration of a single large dose of 50 minims of Lugol's solution—a solution of iodine 5 per cent. and potassium iodide 7½ per cent.—will within 24 hours entirely change the clinical aspect of a case of hyperthyroidism of medium severity. The characteristic stare disappears, the emotional responses lose their uncontrolled violence, and the pulse becomes slower and less tumultuous.

In mild cases a judicious perseverance in the use of small doses of iodine may result in a clinical cure, but it is believed that this is due to the opportunity thus afforded to the thyroid cells to recover their normal function rather than to the direct effect of the iodine itself. In severer cases, if iodine is persisted in for a period of months, even in small doses, the initial improvement is ultimately followed by an acute crisis, manifesting itself by an alarming aggravation of all symptoms, even up to the point of mania.

Now comes the main practical point of the American teaching. Though iodine is not curative, it will in all cases, except in those already maniacal, produce such a temporary improvement as to enable a curative operation for the removal of the thyroid to be undertaken with hardly any risk. Iodine treatment not only relieves the symptoms but it brings about a great reduction in the vascularity of the gland and so reduces the risk of the operation considerably. In the Mayo and Cleveland Clinics, and in the service of Dr. Kanavel in Chicago, the mortality of thyroid operations is now less than 1 per cent. This is a surprising improvement, in view of the fact that many of these patients have already received serious damage to their heart muscle, as indicated by auricular fibrillation. Some authorities believe that the operation in such cases should be preceded by a course of digitalis, but others consider this unnecessary. The vital necessity for a pre-operative course of iodine is universally agreed upon.

THE TWO VARIETIES OF THYROID ENLARGEMENT.

Thyroid enlargements causing serious metabolic disturbance are divided by Plummer into two classes, exophthalmic goitre and toxic adenoma. In the former class there is diffuse parenchymatous hypertrophy and hyperplasia of the thyroid tissue; with exophthalmos, or at least a characteristic stare, a characteristic nervous psychical condition, and pulsating thyroid in which thrill and bruit are present. In the toxic adenoma class there is irregular enlargement of the thyroid, owing to the pressure in it of adenomata which show active hyperplasia of their epithelium. In the toxic adenoma exophthalmos is absent, the thyroid does not pulsate, or only slightly, nervousness, palpitation, tachycardia, vasomoter and gastro-intestinal symptoms and wasting are absent, the blood pressure is raised, and the cardio-vascular disturbances, such as auricular fibrillation and myocarditis, are in the foreground of the clinical picture.

According to Plummer the chemistry of the two contrasted conditions differs essentially. In exophthalmic goitre there is a condition of dysthyroidism due to absorption of a pathological secretion which is insufficiently or not at all iodised, while in toxic adenoma there is an excessive production and absorption of a completely iodised and presumably normal

secretion, a true simple hyperthyroidism. Clinically the distinction between these two classes is not as simple as the foregoing description would indicate, for mixed cases are frequent in which adenomata are found in goitres presenting some or all of the signs of exophthalmic goitre. Graham, of Cleveland, in opposition to Plummer, believes that the chemistry of the tissue of a thyroid adenoma does not essentially differ from the chemistry of the parenchyma of the gland. In his view no distinction can be drawn between dysthyroidism and hyperthyroidism, and he believes that exophthalmic goitre and toxic adenoma are clinical variations of a single disease.

Plummer believes that exophthalmic goitre and toxic adenoma respond differently to iodine in that the former state is invariably for a time benefited, while in the latter the giving of iodine is contra-indicated, except in small doses for a short time as a preliminary to operation. Graham, on the other hand, maintains that in cases of toxic adenoma previously untreated by iodine, the giving of the drug is invariably followed, as in exophthalmic goitre, by a period of improvement. Graham thus sums up his views on iodine administration: When thyroid tissue is hypertrophic and hyperplastic, whether it be the tissue of an adenoma or of the parenchyma of the gland, the administration of iodine is indicated if an operation is contemplated as a necessary preliminary to that operation. If, on the other hand, the thyroid tissue is in a colloidal or resting state, and no signs of hyperthyroidism are present, there is no indication for iodine so far as the thyroid function is concerned, and its ill-advised use may be decidedly harmful.

PREPARATION OF A PATIENT FOR OPERATION.

The introduction by Plummer of preliminary iodine treatment before operation has entirely altered the outlook in exophthalmic goitre, by greatly diminishing the risk of operation and making it easier by reducing the vascularity of the gland. Lugol's solution is universally used in America. On the patient's admission a dose of 50 to 60 minims is given by enema or by mouth, and subsequently doses of 10 to 15 minims are given by mouth for seven to ten days. By this time the basic metabolism has fallen to normal, the pulse has slowed down, and the mental condition has improved. The patient is now operated upon. The day after the operation 50 minims of the solution is given as an enema, and subsequently the small daily doses are continued during convalescence. Lugol's solution should not be given during acute thyroid breakdown or mania, and its prolonged use over a period of months is likely to be followed by an iodine crisis with aggravation of all the symptoms. If auricular fibrillation is present most American authorities advise a course of small doses of digitalis, but others appear to attach little importance to fibrillation, if the iodine preparation has been carried out. Prior to the operation it is usual to give an injection of scopolamine and morphine or of morphine alone.

Anæsthesia.—The usual practice in America is to rely mainly on local novocaine anæsthesia. Ethylene gas, or nitrous oxide, or nitrous oxide and ether are used to supplement the local anæsthetic, especially if the morale of the patient is poor.

MODE OF OPERATION.

It appears to be characteristic of American methods of operation to avoid the dislocation of the thyroid, the operative step upon which Kocher laid such stress. Associated with this difference it is usual in America to avoid the transverse division of the infrahyoid muscles, and even of the platsyma (Crile), in order to preserve the contour of the neck. The usual incision is the collar incision made 2 inches above the sternum, so that its downward displacement during healing shall not bring it over the chest. The skin is undermined up to the hyoid and down to the sternal notch. The thyroid is exposed by a median incision through the deep fascia from the hyoid to the sternum. The infrahyoid muscles and fascia are then retracted by an automatic retracto and other retractors draw the skin flaps out of t way upwards and downwards. Since the thyro has not been dislocated it is impossible to see a ligature the main thyroid arteries and ablation begun by division of the thyroid capsule along i outer margin. Behind this line the removal is entire subcapsular and vessels, often very numerous, a seized as they appear, and from within the capsul Thus the branches of the main arteries are secure instead of the arteries themselves. The lobe carefully dissected from the trachea without exposi that tube. If the trachea is laid bare, according Crile, troublesome coughing will ensue. If the oth lobe is to be removed it is dealt with in the same wa

It is the policy of some of the leading thyroi surgeons to remove at one operation all the glan except a small posterior portion to ensure the safet of the parathyroids and the recurrent laryngea nerves, while others proceed by steps, first ligaturin the superior thyroid artery on one side, and the removing the gland half at a time. It may b interesting to describe these personal variations procedure a little more in detail, and I will take the in the order in which I happened to visit the variou clinics.

A. B. Kanavel, in Chicago, is accustomed to remov nearly the whole gland at one operation and h mortality is very small. He considers that undesi able post-operative symptoms are less likely to occu after such a radical operation than after more limite removal. He gives scopolamine and morphine befor the operation, and ethylene, if necessary, during it course, but novocaine infiltration is also used freel throughout, and especially at the posterior part the gland.

I regret I am unable to describe from persona observation the operative procedure at the May Clinic. Dr. D. C. Balfour, who has done so much i association with the brothers Mayo to develop thyroi surgery, was not operating at the time of my visit nor did I happen to see a thyroidectomy by D J. de J. Pemberton.

Crile, at the Cleveland Clinic, sometimes perform as many as 16 thyroid operations in a morning This is made possible by his own dexterity, by per fection of organisation, and by the trained assistanc which anticipates the operator's desires before h can express them. A proportion of the operations too, consists merely in the ligature of the superio thyroid arteries, or rather of the superior pole the gland. This is done under local anæsthesi through a small transverse incision. The capsule the thyroid is divided in the line of the skin incisio and a branch of the artery is seized. Traction i made upon this, and a mass ligature is then passe around or through the superior pole, so as to secur the main branches of the artery. Perhaps a wee later one half of the thyroid is removed, or the whol gland if the patient's condition warrants it. Loca anæsthesia with novocaine is, if possible, used through out, supplemented if the patient's morale will no stand the ordeal by ethylene or gas anæsthesi Novocaine is used in large quantities, perhaps up t 100 c.cm. of ½ per cent. solution. After the colla incision has been made and the flaps undermine upwards and downwards superficial to the platysma the deep fascia is incised in the middle line an retracted sideways along with the infrahyoid muscles Now comes a characteristic and important step. Th novocaine needle is introduced beneath the capsul and the gland is distended with the novocaine solutio The needle is then plunged into the substance of th thyroid right to its posterior surface, and the solutio again forcibly injected in this situation. Not onl is a very efficient anæsthesia in this way secured, bu the subsequent dissection is greatly facilitated b the separation of the tissue planes. It appears tha the fluid injects all the lymphatics and thus spread widely in the tissues around the gland itself. Cril appears to leave rather more of the posterior surfac of the gland than Kanavel.

F. G. Starr, in Toronto, facilitates lateral retraction by making an incision through the deep fascia along the anterior edge of the sternomastoid on each side. In this city also thyroid operations are very successful.

Thanks to the opportunities afforded by the frequency of thyroid disease in America, the work of American pathologists and the skill of the American surgeons has been specially directed to the thyroid, and a national menace is in process of being effectively met.

In conclusion, I would emphasise the fact that this paper has no pretensions to completeness, nor does it attempt to assign to individuals their relative share in the progress which has been achieved.

Observations ON THE ACTION OF LOBELINE.*

BY F. R. CURTIS, M.Sc., M.B., B.S. LEEDS
AND
SAMSON WRIGHT, M.D., M.R.C.P. LOND.
(From the Physiological Laboratory, Middlesex Hospital Medical School.)

INTEREST in the action of the lobelia alkaloids was stimulated when Wieland[1] first isolated in 1918 a pure crystalline compound from *Lobelia inflata* (Indian tobacco). This was a basic crystalline substance to which the empirical formula $C_{23}H_{29}O_2N$ is assigned. The melting-point is 130–1°C. To this alkaloid the name alpha lobelin has been given. The hydrochloride is the most soluble salt and is the one usually employed in pharmacological studies. The characteristic chemical reaction of the alkaloid is, that on warming with water, aceto-phenone is split off. Wieland has also isolated two other compounds —lobelidine $C_{20}H_{25}O_2N$ and Base B—for which the empirical formula $C_{22}H_{27}O_2N$ was suggested. In a later paper Wieland, Schöpf, and Hermsen[2] have considered the chemistry of two further crystalline alkaloids—namely, lobelanin and lobelanidine. Lobelanin is apparently identical with the Base B previously mentioned, and the empirical formula now assigned to it is $C_{22}H_{25}O_2N$. It should be mentioned that the older lobeline of Dreser [3] probably consisted of a mixture of amorphous alkaloids. Wieland [4] studied the pharmacology of a probably impure lobeline sulphate prepared by Merck. He showed that in narcotised pigeons, after the administration of lobeline, the respiratory centre reacted to a smaller concentration of CO_2 in the alveolar air and blood than normal. Later, Wieland and Mayer studied [5] the action of purified lobeline, and proved it to be a powerful stimulant to the respiratory centre and to produce a great increase in the pulmonary ventilation. It was able to stimulate the breathing after the administration of narcotic and depressant substances like urethane, chloralose, and morphine. Lobelanin was found to have about half the effect on the centre as compared with lobelin.

Since the publication of this paper a considerable clinical literature has accumulated chiefly from American and continental sources. It is claimed that, clinically, lobelin restores regular breathing after overdosage with morphia, after carbon monoxide poisoning,[6] in accidents of anæsthesia, in asphyxia neonatorum,[7] pneumonia, and in stenosis of the respiratory passages. It is also repeatedly stated that lobelin acts specifically on the respiratory centre, and has no side actions on the vomiting centre or on the circulatory system. From the pharmacological point of view lobeline is usually classified with nicotine (Cushny,[8] Sollmann [9]), and by implication has widespread effects in the body. It was thought that as lobeline appeared to be coming into more general clinical use, a careful reinvestigation of its pharmacology would be of value.

* A paper read on Dec. 14th, 1926, to the Section of Pharmacology and Therapeutics of the Royal Society of Medicine.

Methods.—We have carried out experiments on dogs, cats, and rabbits. To avoid the complicating factor of anæsthesia a number of observations have been made on animals which had been decerebrated through a trephine opening in the skull. As the drug is advised in states of respiratory depression numerous observations were made in animals under the influence of ether, chloralose, and morphine, and after damage to the respiratory centre.

EXPERIMENTAL FINDINGS.

The Heart.

The movements of the heart were recorded with a myocardiograph after the method of Oliver and Schäfer,[10] with the chest open and the breathing maintained by means of artificial respiration. Initial and secondary effects may be described.

1. *Initial Effect.*—With doses of 1 mg. lobeline in the cat there is an immediate slowing of the heart—e.g., from 33 beats in 10 seconds to 26 beats. The force of the auricle is considerably diminished. The ventricle is similarly affected, but as a rule to a less extent. There is increased relaxation of the heart between the beats. This cardiac inhibition usually causes an initial fall of blood pressure. Sometimes the blood pressure may rise from the first in spite of the cardiac inhibition. The initial depression may

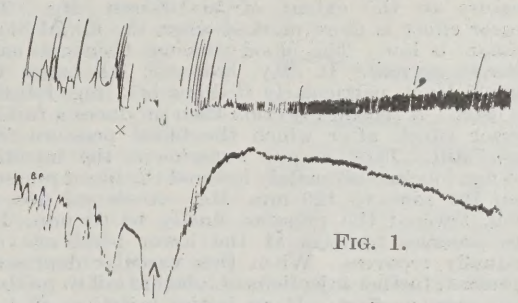


FIG. 1.

Cat. Decerebrate. Upper record = Respiration. Lower record = Blood pressure. Irregular breathing is present. At X an apneusis is shown on which are superimposed a number of small gasps. At the arrow 1 mg. adrenin was injected. Note the rise of blood pressure and the restoration of regular breathing.

be so marked as to cause a profound fall of blood pressure. If the heart is in an enfeebled state, the initial inhibition may arrest it altogether and cause death of the animal within a few seconds. The depression of the ventricle may persist for several minutes, especially if large doses of lobeline—e.g., 7 mg. in the cat—have been administered, but may also occur after smaller doses. It may only wear off gradually with the decline of the general lobeline action (Fig. 5).

2. *Secondary Effect.*—Following on this inhibition, the heart-rate returns to normal or may accelerate further. There may also be an increase in the force of the contraction of auricle and ventricle. With small doses of lobeline the heart gradually returns to its original force, but after larger doses—e.g., 3 mg.—secondary slowing and enfeeblement set in, which are only gradually recovered from.

After section of the vagi the initial slowing is less marked, a fact which suggests that it is partly due to stimulation of the vagus nucleus in the medulla.

After *atropine* the initial cardiac inhibition is abolished or is much less evident, showing itself by trivial slowing. This indicates that the inhibition which persisted after section of the vagi was due to stimulation of the peripheral vagal mechanism. The secondary augmentation of the heart is usually still evident, but we find that sometimes it may be absent. A curious secondary depression may be observed in the auricle. Coincidently with the rise of the blood pressure the auricle is found to relax less between the beats and there is in consequence marked diminution in the extent of the contraction. As the blood pressure falls this excessive state of tone passes off and the extent of the contraction returns to normal. Finally the secondary slowing and diminution of force already noted in the unatropinised animal set in.

Lobeline causes secondary paralysis of the peripheral part of the vagus. If the peripheral end of the cut vagus is stimulated after the administration of lobeline, it is found that a stronger stimulus must be employed to produce cardiac slowing than was necessary previously. Even with maximal stimuli only very slight inhibition is produced. This paralysis persists for several hours and wears off slowly. It is thus seen that the effects of lobeline on the heart are very complex. There is initial stimulation both of the vagus nucleus in the medulla and of the ganglion cells of the vagus in the nodes of the heart. These cells show subsequent paralysis. The acceleration which follows on the initial slowing is probably due to stimulation of the sympathetic ganglia which supply the heart. In addition lobeline has a direct poisonous action on the heart muscle. Even after the administration of atropine, doses of 3 mg. of lobeline leave the heart in a flabby condition and beating slowly and feebly.

Blood Pressure.

With the vagi intact there is often an initial fall of blood pressure—e.g., 10–20 mm. Hg—which is probably due to the cardiac inhibition already described. This is followed by a rapid rise of blood pressure to the extent of 50–100 mm. Hg. The pressor effect is more marked when the initial blood pressure is low. The blood pressure then gradually sinks to normal. It may, however, fall below the original level, particularly if doses of 3 mg. lobeline are used. A second injection then produces a further pressor effect, after which the blood pressure falls lower still. Thus in one experiment the injection of 1 mg. lobeline ultimately lowered the blood pressure from 150 mm. to 120 mm. Hg. A second dose of 3 mg. lowered the pressure finally to 60 mm. Hg. The pressure remains at the lower level or very gradually recovers. When this vascular depression is present, further injections of lobeline fail to produce their pressor effect. If an initial injection of 4 or 5 mg. of lobeline is made, there may be no pressor effect at all. The blood pressure gradually falls to reach a low level. In the pithed animal the rise of blood pressure after lobeline is marked and prolonged. This suggests that the drug has little if any action on the vasomotor centre. The after-fall of blood pressure may in part be due to the secondary cardiac depression already described, but paralysis of the ganglia along the course of the vasomotor fibres may be a more important factor. If the semilunar ganglion is painted with 2 mg. lobeline, stimulation of the cut end of the splanchnic nerve no longer produces the usual rise of blood pressure. Furthermore, when lobeline no longer produces pressor effects the injection of adrenin still causes a rise of blood pressure, indicating that the vasomotor terminals are still intact.

FIG. 2 A.

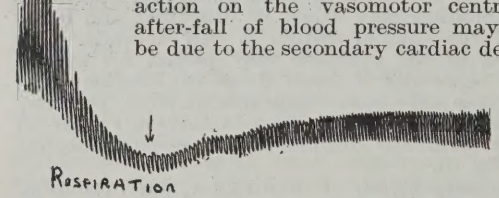

FIG. 2 B.

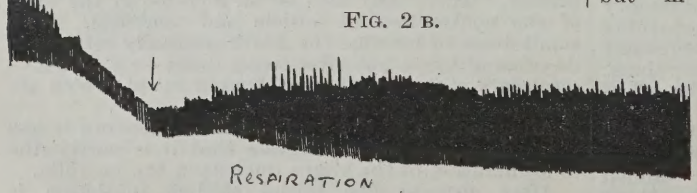

Dog. 6 kg. Ether. Record of respiration. A. Deep ether was administered till the breathing became slow and feeble. At the point marked with the arrow the anæsthetic was discontinued. Recovery took place slowly. B. The experiment was repeated, but at the arrow 1 mg. lobeline was injected. Note the immediate acceleration and increased force of the breathing.

The gradual fall of blood pressure which, as noted above, may be the sole effect of large doses of lobeline is presumably due to paralysis of the vasomotor ganglia without any initial stimulation. The pressor effect of lobeline is less marked in the rabbit than in the cat or dog. It is also abolished to a considerable extent by the administration of large doses of morphine. Lobeline thus first stimulates and then paralyses the ganglia along the course of the vasomotor nerves. Complex blood pressure changes may be produced because of the variable effects on the heart which have already been described.

FIG. 3 A.

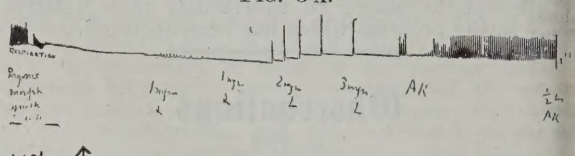

FIG. 3 B.

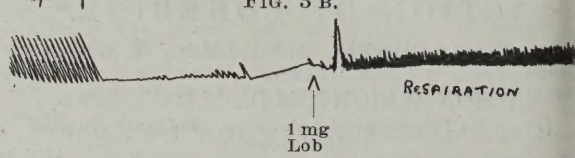


Dog. 6·5 kg. Morphia. A. An additional 10 mg. morphine were injected and apnœa resulted. The successive injection of 1 mg., 1 mg., 2 mg., 3 mg. lobeline only initiated a few ineffective gasps. Artificial respiration was maintained for half an hour after which slow gasps appeared which soon failed. B. Artificial respiration was resumed and at the point marked with the first arrow adrenin was injected. This raised the blood pressure. The artificial respiration was discontinued. The injection of 1 mg. lobeline now initiated regular breathing.

Respiration.

Lobeline markedly stimulates the respiratory centre and causes a considerable increase in the pulmonary ventilation. These effects are well marked in decerebrate animals which have recovered from the effects of the preliminary volatile anæsthetic, or in dogs under light morphia narcosis. We find, however, that the dose which produces respiratory stimulation also produces the circulatory effects already described.

There may be an initial increase in the rate of the breathing without alteration in depth, or even with diminution in depth. This acceleration is by no means constantly obtained, but it appears to be independent of the integrity of the vagi. Following on this, or as the first effect, there is marked increase in the depth of the breathing without change of rate or with slight slowing. In the dog (5–7 kg.) the respiratory effect is well marked with 1 mg. doses of lobeline. The breathing may remain regular, but in the dog especially it is common to find larger and smaller breaths alternating or irregularly interspersed. Doses of 5 mg. in the dog produce violent convulsive respiratory movements in which all the accessory muscles of breathing are involved. The respiratory record then shows marked irregularities; very shallow breaths are present between the very deep ones. Groups of rapid breaths occur. As the initial violent effect wears off a regular deeper breathing persists for ten minutes or longer. There can be no doubt that the threshold of the respiratory centre to CO_2 is lowered by lobeline, because the prolonged and intense hyperpnœa does not give rise to apnœa, but is followed by persistent hyperventilation.

In the cat we have sometimes noted that after the initial stimulating effect has passed off the breathing becomes shallow and slow. This may be associated with stridor. It may, therefore, be due to the bronchoconstriction and increased bronchial secretion which we have found to occur in this animal. In the cat under chloralose an initial inhibition of the respiratory movements of 5–10 seconds

duration may be seen. This is also frequently observed under the same conditions in the rabbit. In this animal there may be either diminution in the extent of the breathing or definite apnœa which is very similar to the apnœa produced by doses of 0·15–0·3 mg. of adrenin. It is unaffected by double vagotomy. The apnœa may possibly be due to bronchoconstriction which prevents the entry of air into the lungs. According to Roberts [11] adrenin apnœa is due to constriction of the blood-vessels supplying the respiratory centre. He has further shown that other vasoconstrictor drugs like pituitrin and barium chloride may cause inhibition of the breathing. It is, therefore, conceivable that the lobeline apnœa may belong to the same category and be due to anæmia of the medulla. In the rabbit in which small doses of lobeline depressed the breathing, the injection of 9 mg. lobeline resulted in increased depth of respiration.

The effects of lobeline were studied in animals under the influence of chloralose, morphia narcosis, deep ether anæsthesia, asphyxia, and after injury to the respiratory centre.

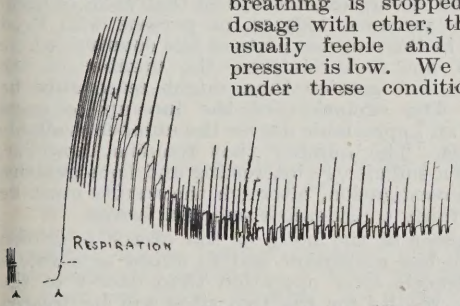
Chloralose.

In animals anæsthetised by the injection of 10 c.cm. of a solution of chloralose saturated at 40° C., the respiratory effects of lobeline are considerably less marked and wear off after a short time. Sometimes two or three deep gasps constitute the whole of the respiratory response. Sometimes no respiratory stimulation whatever results. The apnœa which may occur in animals under chloralose has already been noted.

Ether.

It is very difficult experimentally to produce respiratory paralysis with ether without at the same time depressing the circulation to a great extent. When the breathing is stopped by overdosage with ether, the heart is usually feeble and the blood pressure is low. We have failed under these conditions to restore the breathing with lobeline alone. It is possible that as the circulation is so feeble, adequate concentrations of lobeline do not reach the respiratory centre. We have, therefore, pushed our anæsthesia till the breathing was slow and feeble, and tried the effects of lobeline under these conditions. Fig. 2 shows that recovery is definitely more speedy after the injection of lobeline than in the control animal. Marked acceleration of the breathing results and there is increase in depth subsequently too.

FIG. 4.



Cat. Decerebrate. Artificial respiration. When it was discontinued apnœa was present. 5 mg. lobeline were injected and rhythmic breathing was restored.

Morphia.

In the dog under light morphia narcosis respiratory effects can be obtained with lobeline as marked as in the decerebrate animal. In the cat 1 mg. morphia slowed the breathing to 13 in 130 seconds. The ventilation was very inadequate and the blood became dark in colour. The successive injection of 2 mg. and 3 mg. lobeline increased the rate of the breathing to 30 in 130 seconds. A second injection of 1mg. of morphia while the animal was still under the influence of lobeline caused much less slowing of respiration, and the blood remained a bright red colour. In another experiment 4 mg. morphia produced apnœa; regular though slow breathing was restored by 4 mg. lobeline.

Sometimes, if apnœa is produced by morphia, lobeline may succeed in initiating a few gasping respirations and then apnœa sets in again. Fig. 3 illustrates such an experiment. Artificial respiration had to be resorted to finally. When it was discontinued the apnœa still continued. The blood pressure was raised by the injection of adrenin and then lobeline succeeded in establishing regular breathing.

Lobeline can thus readily overcome doses of morphia which produce respiratory slowing. If complete paralysis of the respiratory centre is present, then lobeline is much less effective. We have already noted that under deep morphia narcosis the pressor action of lobeline is abolished. We are again faced with the difficulty of the low blood pressure. If the circulation is stimulated by adrenin, lobeline is much more potent.

We have carried out a series of experiments in which the brain stem was divided rather low down in the region of the upper pons. We have been able to confirm the observations of Lumsden [12] concerning the alterations in respiratory rhythm which occur. Usually gasping breaths are found to alternate with long apneuses, during which the breath may be held in the inspiratory position for over one minute. The administration of lobeline under these circumstances has produced variable results. It may have no effect at all, or it may shorten the duration of the periods of apneusis. In the experiment illustrated in Fig. 4 the breathing failed after being shallow and irregular, and artificial respiration was commenced. This was discontinued and apnœa supervened. The injection of 5 mg. lobeline almost immediately produced a powerful inspiration. There was an increase in inspiratory tonus. Rhythmic breathing was restored, which was, however, somewhat irregular in character. In Fig. 6 apneustic and gasping breathing were present, and fairly regular breathing was obtained after the repeated injection of 3 mg. lobeline. In some of our experiments we have found adrenin alone, in large doses—e.g., 0·5 to 1 mg.—

FIG. 5.

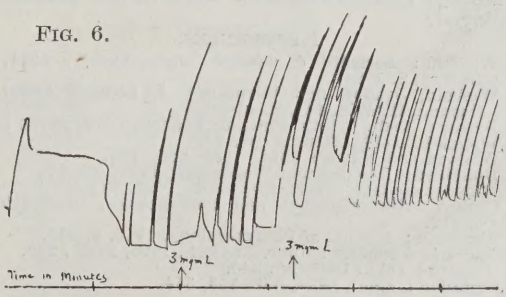
FIG. 6.



Cat. Decerebrate. An apneustic breath is shown which persisted for one and a quarter minutes and was followed by a few gasps and irregular breathing. The repeated injection of 3 mg. lobeline restored rhythmic breathing.

remarkably effective (Fig. 1). It is thus clear that the damaged and partially asphyxiated respiratory centre present after low decerebration may sometimes be restored to regular rhythmic activity by lobeline. Sometimes the improvement in the cerebral circulation which results from adrenin may have the same effect.

Bronchi.

In the pithed cat we find that lobeline usually produces slight constriction of the bronchi. In the rabbit we obtained negative results. These results

are of interest in view of the fact that lobelia is so widely employed in the treatment of asthma. The vagal nerve-endings are subsequently paralysed, so that stimulation of the peripheral end of the vagus no longer produces the usual bronchoconstriction.

Other Effects.

It is claimed that the purified lobeline does not produce vomiting. We found, however, that this is not the case. Doses of 2 mg. or over in the cat not infrequently produce vomiting. The threshold of the vomiting centre is approximately four times as high as that of the respiratory centre. Micturition takes place almost constantly when quite small doses are injected. This is due probably to stimulation of the motor ganglia in the wall of the bladder. Defæcation may result if large doses—e.g., 5 mg.—are employed.

SUMMARY.

Lobeline is thus shown to be a powerful respiratory stimulant, but the doses which are necessary to produce increased breathing have widespread effects on the other systems which resemble in many respects those of nicotine. The drug produces cardiac depression which may be slight and rapidly recovered from, or severe and persistent. Its use in patients with disease of the myocardium should, therefore, be cautious.

Lobeline can overcome to some extent the respiratory depression which is produced by various narcotic drugs like chloralose, morphia, and ether, and it may prove of value in sudden respiratory failure from any cause. The respiratory centre which has been partially asphyxiated and injured as a result of low decerebration may sometimes be restored to rhythmic activity. Our experiments suggest that lobeline may be worthy of more extensive clinical trial, so long as the dangers inherent in the drug are borne in mind. If the blood pressure is low, lobeline will probably be found to be more effective if combined with circulatory stimulants. We have made no observations in man, and are unable to state what doses of lobeline will be found necessary in the human subject, but on the basis of our animal experiments we would suggest that doses of about 10 mg. or more, given intravenously, may be found effective.

The expenses of the above research were partly defrayed by a Government grant, made through the Royal Society to one of us (S. W.). We are indebted to Messrs. Zimmermann for some of the lobeline we employed.

QUEEN ALEXANDRA MEMORIAL.—The highest ratio of contributions towards this memorial, which is to take the form of supporting the work of the Queen's nurses, is 21·6 per cent. in Peeblesshire; the lowest, 0·89, in London. In England, Rochdale is at the head of the list with 3·5 per cent.

EXTENSIONS of the Dudley-road Hospital, belonging to the Birmingham Guardians, which have just been opened, have, it is claimed, made it the largest institution of its kind outside London. Since it was opened in 1887 for the treatment of infirm, bedridden, and chronic cases it has undergone many changes. During the war it was a military hospital, but since the guardians resumed possession it has become a general hospital where patients are treated, not as subject to the Poor-law, but as members of the general public. Last year 13,000 patients passed through the hospital.

CANCER OF THE UTERUS.

A STATISTICAL STUDY; WITH SPECIAL REFERENCE TO THE RESULTS OF OPERATION.

BY CLARA STEWART, M.B., B.S. LOND.,
AND
MATTHEW YOUNG, M.D. GLASG.

(*From the Department of Pathology and Bacteriology, University of Leeds, and the Statistical Department of the Medical Research Council.*)

Introductory.—The data on which this investigation is based comprise all the patients with cancer of the cervix and cancer of the body of the uterus amongst those operated on in the Women's Hospital, Leeds, and Gynæcological Wards of the General Infirmary, Leeds, during the decennium 1911–20, in which the carcinomatous nature of the growth was confirmed by histological examination. The series embraces in all 214 cases of cancer of the uterus, of which 176 were located in the cervix and 38 in the body. The post-operative histories of all these patients, with a few exceptions, have been traced for five years at least after the operation, or till the date of death if this occurred under five years thereafter. Some who survived the operation for five years have been traced as still alive for much longer periods, as will be described later. In a certain number of patients—namely, 23—or practically 10 per cent. of the total series, it was impossible to trace the complete post-operative histories. The proportion of untraced cases may appear relatively large, but in view of the fact that the area of country from which the patients were derived is very extensive, and that most of them were either servants, lodgers, or persons who lived in villages in the remoter parts of the country, where letters did not find relatives, the number of the untraced is not greater than might reasonably be expected. The exclusion of the incomplete cases reduces to an appreciable degree the number available for analysis. The number that remains, however, constitutes a sufficiently interesting and homogeneous series for investigation, although the results must be subject to fairly considerable sampling errors.

Since cancer of the body of the uterus is known to be much less malignant and to afford as a rule a better prognosis after operation than cancer of the cervix, the results for the two sites will be treated separately, but will be placed in apposition for comparative purposes.

Cancer of the Cervix Uteri.

The majority of the patients with cancer of the cervix that come under review may be classified into two broad groups: (1) those undergoing a complete operation—namely, a Wertheim, an abdominal hysterectomy, or a vaginal hysterectomy; (2) those who were treated by what may be termed palliative methods, the curette, cautery, or who were merely subjected to exploratory laparotomy. Into the first group fall 116 patients, in 12 of whom the post-operative histories could not be ascertained. Of the second group, comprising 52 cases, seven were not traceable. The cases in this group are assumed to be those that were either unsuitable for a radical operation or inoperable.

In addition to these two comprehensive groups there were eight patients with cervical cancer; five of these, though curetted, would not submit to radical operation, one had an amputation of the cervix uteri, another an amputation of the stump (cervix) for cancer following a former operation abroad for removal of the body of the uterus, evidently for cancer three years previously, and another had an operation of an indeterminate nature (probably hysterectomy, as death occurred in hospital). The distribution of the subgroups of cases of cervical cancer treated by the several operative methods according to duration of post-operative life is shown in some detail in Table I.

TABLE I.—*Showing the Duration of Post-operative Life in Patients with Uterine Cancer according to Nature of the Operation.*

* Presumably inoperable. † Includes one curetted only; omitted from survivorship table.
‡ Includes one ‖ Includes two } who died in less than five years after operation but exact duration of post-operative life unknown.
§ Includes one with nature of operation uncertain.

Cancer of the Corpus Uteri.

As already mentioned, particulars were obtained of 38 cases of cancer of the body of the uterus. All the patients were stated to have undergone hysterectomy or panhysterectomy with the exception of two, of whom one was merely curetted and the other had an operation of unrecorded nature. The post-operative histories were traced for five years after operation or till the date of previous death in all except three of the 36 patients undergoing hysterectomy, leaving 33 cases available for analysis. The number is relatively small, but the results have been tabulated for purposes of contrast in a manner similar to that adopted for the cases of cervical cancer.

Duration of Post-operative Life in the Different Groups of Cases.

We now come to consider and compare in greater detail the characteristics of the group of cases of cervical cancer treated radically and that treated by palliative measures. A table was prepared, but is not published, showing for these two groups separately the distribution of durations of post-operative life when the patients were arranged in decennial age-groups, 25–34, 35–44, &c., and the percentages of the totals traced in these age-groups who survived three years and five years respectively after operation. The numbers in the different decades of life at operation were small, however, and no emphasis can be laid on such differences as appeared to exist in the percentages of survivals therein. Amongst the 104 of all ages who were operated on radically and who were traced for five years at least after operation or till the date of earlier death, 32, or 30·8 per cent., survived the operation for three years and 24, or 23·1 per cent., for five years. Of those between the ages 35 and 44 years at operation who survived the event five years at least, one was alive eight years and another 11 years afterwards. Amongst those in the decade 45 to 54 years at operation, one was still alive at eight and a half years, two at nine years, one at ten years, one at 11 years, and another at 12 years thereafter. Four survived the operation five years but died later, one in the sixth year, one in the seventh year, and two in the eighth year. As the cause of death in three of these cases, including that of a patient dying before the completion of the seventh year and another of one dying just under eight years after operation, was cancer, freedom from recurrence for five years after operation obviously cannot be assumed to indicate a cure as is frequently asserted. A feature of special interest in the table was the high mortality-rate from the effects of the operation; 20, or 17·2 per cent., of the 116 patients who had a radical operation died in hospital. Of the 45 patients treated by palliative measures, one only in the age-group 35–44 years survived the operation for three full years.

The distribution of the patients with cancer of the body of the uterus according to duration of post-operative life for the decennial age-groups was also tabulated. The numbers in the different decades of life at operation were again too small to warrant any conclusions regarding differences therein in the percentages that survived for three years or for five years respectively. Of those who survived the operation for five years, two were still alive at eight years, one at ten years, one at 12 years, and a fourth at 13 years thereafter. Two survived the event five years but died subsequently, one in the seventh and the other in the eighth year, both of recurrence of the disease.

The results in the different groups can be brought into greater contrast by means of survivorship tables. In Table II. are shown in separate columns survivorship tables for the first five years after operation for: (*a*) the group of patients with cancer of the cervix uteri who were treated by radical operation; (*b*) the patients treated by palliative measures; and (*d*) the group of patients with cancer of the corpus uteri who were treated by radical operation. For comparison with these, another survivorship table for cases of cancer of the cervix uteri is entered in column (*c*). This table is a modified form of a survivorship table which is contained in Dr. Greenwood's (1926) report to the Ministry of Health on the Natural Duration of Cancer, and which shows the number

* Greenwood, M. (1926), vide ref. † No. of observations.

of survivors at each year for six years from the reputed date of onset of first symptoms in a series of 1749 patients with cervical cancer who received no operative treatment. The patients under review were only treated after the symptoms had been present on the average for a period of from nine to 14 months, or approximately a year. The proper comparison of the survivorship tables for the hospital cases is thus not with the survivorship table for the untreated cases as it is given in the report mentioned, but with a table constructed with the untreated survivors at the end of one year—namely, 1248 out of the original number 1749, taken as the base line or 1000. A comparison of columns (*a*) and (*c*) of the table representing the survivorship amongst the groups of the radically treated and the non-treated cases of cancer of the cervix respectively shows the very favourable results that ensue from treatment by radical operation. Notwithstanding the considerable mortality in the first post-operative year due to the effects of the operation, which has been described as 172 per 1000, the number of survivors at the beginning of the second year after operation is significantly in excess of that in the comparable group amongst the untreated. At the beginning of the fourth year after operation the number of survivors from the original number, or radix, 1000, in the group treated by radical operation is almost four times, and at the beginning of the sixth year fully nine times, the comparable numbers shown in the untreated group. Column (*b*) of Table II. shows the rapid elimination by death of the patients in the group treated by palliative measures, which consists largely of the cases that may be regarded as unsuitable for operation. At the beginning of the second year after operation the proportion of survivors in this group is less than half that shown amongst those radically treated, in spite of the high mortality in the latter group from the effects of operation. Out of 1000 undergoing operation, none survives to begin the fifth year after operation, whereas 250, or one-fourth of the original number of those treated radically, survive at the corresponding stage.

No survivorship table for patients with cancer of the body of the uterus allowed to run its natural course is available for comparison with column (*d*) of Table II. As the total number of cases in this group is relatively small, the standard errors attached to the numbers of survivors at the beginning of each successive year out of the original 1000 are considerable, and probably small stress can be laid on the differences that are shown, but it seems worthy of note that whereas 515 of the original 1000, or 51·5 per cent., survive the third year in cancer of the body; the corresponding proportion in cancer of the cervix radically treated is 308, or 30·8 per cent. This difference is statistically significant. The percentage surviving five years is 39·4 when the site is the body, and 23·1 when the site is the cervix. This difference, though suggestive, cannot, however, be judged significant on the numbers available.

There are certain other points for which data are available for comparison in the two groups of patients: (1) those with cancer of the cervix uteri with the two subgroups, the radically treated and the inoperable cases; and (2) those with cancer of the corpus uteri treated radically. These are: (*a*) the average age at operation; (*b*) the alleged duration of symptoms; (*c*) the relationship to childbirth; and (*d*) the histological nature of the primary growth.

The Average Age at Operation.

Of the 116 patients with cervical cancer undergoing radical operation the mean age at operation was 46·7 ± 0·9 years, the standard deviation of the age distribution 10·2 years, and the coefficient of variation 22 per cent. For the 52 patients treated by palliative measures, the mean age at operation was 49·8 ± 1·6 years, the standard deviation 11·5 years, and the coefficient of variation 23 per cent. For the whole series of patients with cancer of the cervix uteri the mean age at operation was 47·4 ± 0·8 years. The variability in the distribution of ages in the two groups, the radically treated and the palliatively treated, is thus practically identical, and though the mean age is three years higher in the latter than in the former group, such a difference cannot be judged significant in view of the size of the errors of random sampling.

The mean age at operation of the 38 patients with cancer of the body of the uterus was 52·4 ± 1·0 years, and the coefficient of variation 12 per cent. The mean age in this group is thus five years higher than that of the group of patients with cancer of the cervix, a difference which is certainly significant, indicating that carcinoma of the body occurs on the average later in life than cancer of the cervix.

Alleged Duration of Symptoms.

In 17 out of the 116 patients with cervical cancer who were treated by radical operation, no estimate of the duration of symptoms could be obtained. The average duration in the remaining 99 patients was 10·3 ± 1·3 months. The limits of the range were less than a month and 84 months. The wide degree of dispersion in the series of durations is shown by a standard deviation of 13·0 months, and a coefficient of variation of 126 per cent. Of the 52 patients receiving palliative treatment, the alleged duration of symptoms was ascertained in 49 instances. The average duration in these was 9·0 ± 1·1 months. The variability in duration was somewhat less than in the other group. Though very slight reliance can be placed on the reputed duration of symptoms, and no significance can be attached to the difference of one month in the average durations of symptoms in the two groups, the radically treated and the palliatively treated, it is of interest to note that the mean reputed duration of signs of the disease preceding operation is not greater in the group of presumably inoperable cases than in the group not considered too far advanced for radical treatment.

As in patients with cervical cancer, the alleged duration of symptoms in patients with cancer of the body of the uterus was very variable. The limits of the range in reputed duration were one month and 48 months, and the coefficient of variation was 79 per cent. The average value was 14·0 ± 2·2 months. This cannot be said to differ significantly from the average duration in the cervical cases.

Relationship of Childbirth to Cancer of Uterus.

There is now a considerable amount of evidence to show that childbirth predisposes to cancer of the cervix of the uterus, apparently from the trauma incident to this process, though no relationship appears to exist between it and cancer of the corpus uteri. The distribution of the two separate series of patients with cancer of the cervix and body of the uterus respectively in the present data according to marital condition and the number of children borne is shown in Table III. Miscarriages, though recorded, were excluded from consideration, as information regarding these was believed to be very unreliable. Amongst those with cancer of the cervix whose pre-operative histories were traced, the proportion of nulliparous women was 17 out of 158, or 10·8 ± 2·5 per cent., a result in close agreement with that described by various other observers. The proportion of nulliparæ amongst the cases of cancer of the body of the uterus was 15 out of 37, or 40·5 ± 8·1 per cent. The difference is 29·7 ± 8·5 per cent., which is statistically significant and indicates a quite definite relative preponderance of parous women in the former group.

Of the total cases of cancer of the uterus in the series under observation, about 96 per cent. occurred at ages over 30. The numbers of single and married women (including widows) at ages over 30 in Leeds in 1921, as given in the census, are 19,433 and 97,299 respectively, so that single women form 16·6 per cent. of the total women in this period of life. Estimates of the proportion of sterile marriages in the general population have been given by various

observers. In the report on the Fertility of Marriage based on data collected for England and Wales at the census in 1911, the proportion of childless marriages in families of completed fertility is given by Dr. Stevenson (1923) as 16 per cent. For the same period in Scotland the corresponding figure is stated to be 11·5 per cent. If it be assumed that the figure for England and Wales—namely, 16 per cent., which it is of interest to note is in remarkably close agreement with the figure given by Matthews Duncan (1866) for Scottish data in 1855, holds for Leeds an estimate of the nulliparæ among married women over 30 years of age in this city may be obtained. This figure, added to the total of single women corrected for incidence of parity therein, would give the total number of nulliparous women over 30. As illegitimate births in Leeds form fully 5 per cent. of the total births, some reduction in the single women to allow for parity would appear to be necessary. Unfortunately, suitable data to make this adjustment are not available. The correction required may not be so considerable as appears at first sight, however, as many single women who have borne children in early life will probably be married by the time they attain the age of 30. If it be assumed that to obtain a rough estimate the nulliparæ may be computed in the way described but without any adjustment of the number of single women, nulliparous women would appear to form 30 per cent. of the female population over 30 years of age in Leeds. The assumption that even as many as 10 per cent. of the single women are parous, probably an excessive figure, only reduces the estimated proportion of nulliparæ amongst women over 30 years to 28 per cent. Such estimates can only be considered very rough approximations, but it is interesting to note that the proportions of nulliparous and parous women in the female population in Leeds above 30 computed in this way diverge so little from the corresponding proportions in the series of patients with cancer of the body of the uterus that they cannot be adjudged significantly different, as the differences fall within twice the range of their standard errors, whereas the proportion of nulliparous women amongst the patients with cervical cancer is considerably less than in the female population at the corresponding ages.

At various times suggestions have been put forward that the number of children borne has some association with the incidence of cancer of the cervix uteri. The data available are not sufficiently numerous to investigate this question fully, but it seems to be of interest to note that the average number of children per married woman amongst those traced with cancer of the cervix was 4·86 ± 0·29, whereas the average number amongst the married women with cancer of the body was 2·43 ± 0·55, a significant difference. The period of reproductive life, it must be admitted, is doubtless incomplete in some of the patients, but any such inequality in the two groups would tend to exaggerate the difference in the mean numbers of pregnancies, as the average age of the patients with cancer of the body of the uterus has been shown to be about five years higher than that of those with cancer of the cervix.

The Histological Nature of the Primary Growth.

As a detailed histological examination of the growth had been made in all the cases under review, a brief account may be given of the incidence of the different types, though the data do not warrant an attempt to draw conclusions regarding any apparent association between type of tumour and post-operative results. Of the 176 cases of cancer of the cervix uteri, 140 were classed as squamous celled, 24 as spheroidal celled, 1 as basal celled, and 11 as adenocarcinomatous. The first and second of these groups differ only in respect of the presence or absence of epidermoid whorls and keratinisation, and are really the same tumour with varying grades of differentiation. It is probable that in nearly every case epidermoid whorling could have been demonstrated had a sufficiently prolonged and detailed examination been made. No prognostic significance could be attached to the differing histological pictures within this group in the present series. The case of basal celled cancer not only showed no evidence of whorling or keratinisation, but resembled in a quite remarkable way rodent ulcer of the skin. This patient, who was aged 44, was still alive five years after operation (Wertheim), but died soon after from pneumonia.

Of the group of 11 patients with adenocarcinoma, 9 were traced, and of these 3 died under a year, 1 under two years, and 1 under four years, while 4 are still alive at periods varying from 5 to 11 years from operation. This is a good result, but the numbers are too few to warrant generalisation. In several of the specimens squamous metaplasia was present.

All the 38 malignant tumours of the corpus uteri in the series were adenocarcinomatous in type except five, which were spheroidal celled. These five occurred in patients who were between 50 and 56 years of age at the time of operation, with symptoms reputed to have been present for periods varying from two months to a year. Four of these patients were treated by panhysterectomy, with the result that all died within 18 months thereafter, one with recurrence in the bowel.

Summary and Conclusions.

The foregoing paper contains an analysis of the post-operative histories of, and certain relevant features such as age distribution, reputed duration of symptoms, and parity in, 176 hospital patients with cancer of the cervix uteri and 38 patients with cancer of the corpus uteri. Though the numbers available are, perhaps, not sufficient to warrant any dogmatic statements on the various points investigated, the results seem sufficiently reliable to give some general indication as to what may be expected in larger series of cases. The main points that emerge from the inquiry are :—

1. The results of radical operation in cancer of the cervix uteri must be considered very favourable notwithstanding the relatively high operative mortality. The extent of the gain from this form of treatment may be gauged from the fact that in the group so treated the number of survivors at the

beginning of the fourth year after operation is nearly four times, and at the beginning of the sixth year after operation fully nine times the numbers in the comparable groups in a long series of cases permitted to run their course without treatment.

2. Though the post-operative survivorship amongst the patients with cancer of the corpus uteri treated by radical methods cannot be compared with that in a non-treated series, as such a series is not readily available, the figures suggest that the end-results in these patients are more favourable than those in patients with cancer of the cervix treated radically.

3. The average reputed duration of symptoms prior to operation in the patients with cancer of the cervix who were treated radically diverges very slightly from that in the patients who were considered unsuitable for operation; the average duration of signs in all the patients with cervical cancer is about four months less than for the patients with cancer of the body, but this difference cannot be judged significant.

4. The mean age at operation of the patients with cancer of the corpus uteri has been shown to be about five years higher than that of the patients with cancer of the cervix. The average durations of symptoms in the two groups are not significantly different, so it is evident that cancer of the corpus uteri appears later in life on the average than cancer of the cervix uteri.

5. The proportion of nulliparæ amongst the patients with cancer of the cervix uteri is 10·8 per cent. This is significantly lower than the proportion amongst those with cancer of the corpus uteri—namely, 40·5 per cent. The average number of children per married patient with cancer of the cervix uteri is 4·86, which is twice the average number borne by patients with cancer of the corpus uteri. These results support the alleged association between childbirth and cancer of the cervix.

We are indebted to the gynæcological surgeons of the General Infirmary and the Women's Hospital, Leeds, for permission to investigate their cases.

CLINICAL FEATURES AND TREATMENT.

BY R. J. McNEILL LOVE, M.S. LOND., F.R.C.S. ENG.,

SURGICAL ASSISTANT TO THE LONDON HOSPITAL, E.; EMERGENCY SURGEON, MILDMAY MISSION HOSPITAL, E.

THIS paper is based upon 51 cases of acute pancreatitis, which have been treated at the London Hospital during the years 1911-24. In considering the clinical aspect of this condition I propose to deal with the general features, symptoms and signs, treatment and after-results, in as far as the latter are obtainable.

General Features.

Although acute pancreatitis is usually considered to be commoner in men, in this series the incidence was reversed, as out of 51 collected cases, 31, or 60·8 per cent., were females. The youngest member was a girl of 11, and the oldest a female of 73. The previous history in most cases was very interesting, indicating that the condition is one which is progressive, and that many attacks may occur before the final abdominal catastrophe. The previous histories may be summarised as follows:—

Previous similar attacks	31
No previous attacks	15
Inconclusive history	5

One obvious fallacy in compiling the above statistics is that the patient may confuse abdominal pain due to other causes—e.g., cholecystitis—with pain due to pancreatitis. However, the difficulty was realised while analysing the histories, and guarded against as far as possible.

The series included one case in which a laparotomy was performed for abdominal pain of obscure origin. A condition of "chronic pancreatitis" was diagnosed and the abdomen closed. One month later the patient was hurriedly returned from convalescent home with an attack of acute hæmorrhagic pancreatitis, which was confirmed at post-mortem. An even more striking instance of the recurrence of the condition with increasing severity may be quoted in more detail:—

Case of A. B., brewer's drayman.

1907: Aged 36. Was suddenly seized with acute abdominal pain. The diagnosis of "acute alcoholic gastritis" was made, and the patient attended the medical out-patient department. He was discharged a few weeks later as cured.

1910: Drank a glass of cold water and was suddenly seized with severe pain, similar to previous attack, vomited several times, and was admitted to hospital. On examination some tenderness and rigidity was present over the gall-bladder area. The symptoms abated and he was discharged.

February, 1924: Third severe attack while rolling barrels. Pain so acute that patient became unconscious. On admission to hospital shock was well marked, cyanosis was present, and rigidity was entirely absent. A diagnosis of acute pancreatitis was made, and the abdomen opened through a right paramedial incision. Fat necrosis was general, the pancreas was swollen and œdematous, and the gall-bladder was distended, but no stones were present. Cholecystotomy was performed and the patient recovered.

July, 1924: The patient was seized with a fourth attack similar to those described above. He was admitted moribund and died shortly afterwards.

Symptoms and Signs.

The onset of the condition is as sudden as that of any abdominal emergency, and resembles a perforated ulcer, in that the patient can usually describe precisely what he was doing at the time of onset. Pain is severe and in proportion to the severity of the attack; hence in severe attacks the patient may be collapsed and unconscious. The pain is epigastric in origin, and usually radiates through to the back. In the early stages the temperature is depressed in proportion to the shock, and the pulse is correspondingly slow and feeble. As shock passes off, the pulse improves and the temperature rises to slightly above normal, while finally both may be influenced by the onset of peritonitis.

General cyanosis, particularly of the face and extremities, was noted in 12 cases of this series; as some cases were erroneously diagnosed it is reasonable to presume that cyanosis may have been present but was unrecognised. Probably this cyanosis is due to the restricted movements of the diaphragm, consequent on subdiaphragmatic irritation or spasm of the crura. Localised cyanosis, which has occasionally been noted—e.g., in the loin—was not recognised in any of these cases.

Abdominal rigidity is a variable factor and is somewhat paradoxical, in that it varies inversely to the severity of the condition. Thus in severe cases shock is so marked that the musculature is generally relaxed, and protective rigidity is thus in abeyance. When shock subsides rigidity asserts itself, the muscles reacting to the inflamed peritoneum covering the pancreas. In cases of less severity or more localised infection, rigidity may be board-like from the commencement, particularly in the epigastrium. Vomiting occurred in practically all the cases, and was occasionally very protracted. Slight jaundice was noted in two cases. The presence of a tumour was noted in nine of the cases under review, five of these were localised rounded swellings in the upper abdomen, three in the left hypochondrium, and two in the epigastrium, the remaining four being indefinite in nature. Localisation of infection would be expected to produce a palpable swelling; in other cases where merely induration and turgidity are present, the

possible rigidity and probable obesity mitigate against detection of the pancreatic enlargement.

Special tests are, naturally, of little value in abdominal emergencies. Glycosuria may readily be recognised, but is uncommon, being present in only three out of 30 cases. The absence of glycosuria is explained by the fact that the islands of Langerhans escape destruction. Loewi's mydriatic test, consisting of installation of adrenalin in the eye, a positive result being obtained if the pupil dilates (possibly eccentrically), was definitely obtained in five cases. Apparently this under-estimates its utility, as Waring and Griffiths [1] found it positive in three out of four cases of acute pancreatitis. The diastase index, normally 10 to 20 units, has obviously little diagnostic value in emergency surgery, although in one case in this series 100 units were present. Also other acute abdominal conditions may diminish the value of this test by raising the index; thus Barling records a case of pneumococcal peritonitis with a diastase index of 50 units.[2]

Treatment.

Considerable discussion has revolved around the question of treatment, and in considering the treatment of any condition complicated by more than one pathological lesion, due regard must be paid to all abnormalities present. The most obvious pathological condition to be commonly associated with acute pancreatitis is cholecystitis, usually indicated by the presence of gall-stones. Hence this question is considered in two groups, that is, cases with gall-stones present and those in which they are absent. This is admittedly an arbitrary distinction, as cholecystitis may be present without stones which may not yet have formed, or although formerly present, may have passed along the ducts. Much emphasis has been laid upon the association of acute pancreatitis and gall-stones, the association of which has possibly been over-estimated. In 14 cases published by Waring and Griffiths, gall-stones were present in only two cases; in this series, in which adequate notes were obtainable, gall-stones were present in 25 out of 49 cases, that is, 51 per cent.

With regard to the converse association, it is stated that in 25–30 per cent. in which operation is performed for gall-stones, some degree of pancreatitis is present. It must, of course, be admitted that in any case it is extremely difficult to recognise at operation a minor degree of pancreatic involvement. Forty-seven cases were submitted to operation, the remaining four not recovering sufficiently from shock or toxæmia to allow of surgical interference.

For the purpose of comparison the operative measures may be divided into the following three procedures: (1) drainage of gall-bladder or bile-ducts, usually combined with drainage of the peritoneal cavity; (2) drainage of the peritoneal cavity alone, with or without exposure of the pancreas, by tearing through its covering of peritoneum; (3) incision into and drainage of the pancreas through the abdominal wound with or without the two previous procedures.

Results.

Following the scheme outlined above we find the results as follows:—

GROUP 1.	*Gall-stones Present.*		*2. Absent.*	
	R.	D.	R.	D.
Drainage of gall-bladder or bile-duct	12	9	4	1
Drainage of peritoneal cavity	3	0	9	3
Incision and drainage of pancreas	0	1	1	4
	15	10	14	8

R.= Recovered. D.= Died.

The total mortality of cases submitted to operation: 18 died and 29 recovered—i.e., 38·3 per cent. The total mortality of all cases (including four too ill for operation), 22 died and 29 recovered—i.e., 43·1 per cent.

[1] Waring and Griffiths: Brit. Jour. Surg., January, 1924.
[2] Barling: Brit. Med. Jour., April 28th, 1923.

In comparing the above groups we find the results of each operative procedure as follows:—

	R.	D.	Mortality.
Drainage of gall-bladder or bile-ducts	16	10	38·5 %
Drainage of peritoneal cavity	12	3	20 %
Incision and drainage of pancreas	1	5	83·3 %

In commenting upon the above results, although the mortality of drainage of the gall-bladder or biliary passages is high, yet it seems more reasonable to drain the biliary passages where definite pathological changes are found, especially if local conditions render this easy of accomplishment. It is well known that cases have occurred in which a stone is impacted in the ampulla of Vater, and which appears to be the actual cause of acute pancreatitis, and therefore, if stones are discovered, steps should be taken to exclude this possibility.

Distension of an apparently healthy gall-bladder is frequently found, and is to be expected under these circumstances, when the head of the pancreas is swollen and œdematous; therefore mere distension with no obvious pathological abnormality can rarely be considered an indication for cholecystotomy. The above figures indicate that the most favourable results are obtained by mere drainage of the peritoneal cavity. In most cases where this was the only operative procedure, evidence of cholecystitis was absent, and hence there was no indication for further interference.

One striking feature of these results is the poor prognosis in cases in which the pancreas was incised and drained. This is probably due to several reasons, of which may be mentioned: (1) incision of the pancreas favours local hæmorrhage and adds trauma to infection; (2) non-infected areas in the pancreas are exposed to infection, hence infection tends to become more widespread; (3) injury of the pancreatico-duodenal arteries may occur, interfering with the blood-supply of the duodenum, and cases of duodenal fistulæ have been reported after this procedure. Hence it appears that in the light of our present knowledge the line of treatment commonly indicated is peritoneal drainage, the peritoneum over the pancreas being first incised, it being advisable to bring the drainage-tube out through a separate puncture rather than through the laparotomy wound, owing to risk of the wound breaking down as a result of the action of pancreatic enzymes.

Suprapubic drainage may reasonably be added in cases of widespread infection. If gall-stones or other evidences of cholecystitis are present, then cholecystotomy should be combined with the above if the general and local conditions are satisfactory.

Recently it has been advised to secure retroperitoneal drainage of the pancreas by means of a subcostal incision in the left loin, which has the advantage of obviating the risk of peritoneal infection by manipulation and drainage-tubes. This line of treatment is supported by the above statistics, which suggest that in the absence of a diseased gall-bladder, peritoneal drainage gives good results; therefore, if the patient is sufficiently fit, and the gall-bladder appears to be healthy, the ideal treatment would appear to be closure of the laparotomy wound and the establishment of retroperitoneal drainage.

After-treatment.

Owing to the well-known effect of pancreatic discharges on tissues with which they come in contact, immediate protection should be afforded to the wound by means of some mineral fat. The puncture wound for the drainage-tube should be kept separate from the laparotomy wound. In two cases of this series re-suture of the laparotomy wound was necessary, and in other cases it was noticed during convalescence that the wound bulged, ventral herniæ subsequently developed. As a result of the general infection of the pancreas, and consequent alimentary disturbances, pancreatised food or some form of artificial pancreatic secretion should be administered as long as necessary.

Although uncommon, glycosuria occasionally persists after an attack of acute pancreatitis, in one case amounting to 2·5 per cent. one month after operation. Possibly chronic pancreatitis had previously depressed the islands of Langerhan's and predisposed to acute infection. Hence, possibility of glycosuria as a sequelæ should be borne in mind, and, if necessary, suitable medical régime instituted.

After-results.

It has already been indicated that this condition is one which tends to be recurrent and frequently progressive, the subsequent attacks commonly increasing in severity. In the case previously outlined the fourth definite attack was fatal, and in cases which recover with surgical assistance one would expect to find that, as the cause of the condition is incompletely understood, and, therefore, presumably continues, recurrences are likely to occur.

In one case of the series a recurrent attack occurred while a patient was still in bed, 22 days after cholecystotomy had been performed. The pain had been so severe that morphia was necessary. Reference has already been made to a case which returned from convalescent home with a further and fatal attack of acute pancreatitis.

Twenty-eight cases with at least one year's interval after operation have been traced, and evidence obtained regarding their after-history. Of 25 conclusive histories, no less than 16 suffered from subsequent attacks. Obviously the same fallacy exists in obtaining information regarding previous attacks, in that the patient may mistake pancreatic pain for pain of other origin. This danger was recognised and obviated as far as possible, and the characteristics of pancreatic pain are such that once actually experienced its subsequent recognition is probable. Again, in two cases in which cholecystectomy was performed typical attacks of pancreatic pain recurred, and in these cases pain due to cholecystitis or gall-stones were excluded.

Summarising the after-histories we obtained the following results:—

	Gall-stones Present.	*Absent.*
Recurrent attacks	13	3
No recurrent attacks	3	6
Inconclusive	2	1

The above figures are merely sufficient to suggest one or two features, perhaps the most striking is that the majority of cases of acute pancreatitis tend to relapse, and subsequent attacks are to be expected. Also the risk of these subsequent attacks appears to be greater when associated with cholecystitis as indicated by the presence of gall-stones, suggesting that when once pancreatitis infection is established infection of the biliary passages predisposes to reinfection of the pancreas.

Summary.

(1) Acute pancreatitis is a progressive condition, less severe attacks are frequently unrecognised, but the condition tends to culminate in an abdominal catastrophe.

(2) Drainage of the pancreatic region appears to be the essential line of treatment if pathological condition of the gall-bladder are present, then cholecystotomy may be performed as well. In suitable cases retroperitoneal drainage would be expected to give good results. Incision and drainage of the pancreas is not to be recommended.

(3) Immediate care should be taken to protect the wound after operation, and drainage-tubes should be inserted through special puncture wounds.

(4) Recurrence of attacks is to be expected, particularly when pathological conditions of the gall-bladder are present.

In conclusion, I must thank various members of the staff of the London Hospital for permission to include among statistics cases under their charge.

ULTRA-VIOLET RADIATION IN CŒLIAC DISEASE.*

BY RALPH G. MICHELMORE, M.B., B.S. LOND.
HON. PHYSICIAN, SIDMOUTH COTTAGE HOSPITAL.

LITTLE of clinical value has been hitherto added to the original description of cœliac disease by Gee in 1888. The essentials of the following case may best be shown by reference to the weight chart here given and to the details of the condition present in July, 1923.

At the age of 6 years the child weighed 29 lb. only—i.e., the equivalent of a child of 2 years. Her height was 41 in., and body-height 22¾ in.

Absence of organic disease, an abdomen enlarged to a circumference of 20 in., a clean tongue and capricious appetite, five or six whitish fatty stools daily containing 46 per cent. of total fat of the dried material, and its onset at the age of 3 years established the diagnosis of cœliac disease, the child having been born at full term, 7 lb. in weight, and subsequently breast fed for ten months.

Subsequently attacks of colic, vomiting, and diarrhœa occurred, and an anæmia in January, 1925 (R.B.C., 3,500,000, Hb 70 per cent., and C.I. = 1), was demonstrated.

Apparently the disease is very seldom fatal, and the symptoms pass off during the later years of childhood; growth occurring to fair stature with freedom from symptoms on an ordinary diet.

Types of the Disease.

Two types of the disease are described: (1) The diarrhœic, where the stool resembles that of sprue, large, pale, and offensive, with fat as fatty acid. (2) Non-diarrhœic, where the stool is formed, coloured, and not offensive, with fat chiefly in form of soaps.

Post-mortems of other cases show no wasting of the intestinal mucous membranes or of Leiberkühn's follicles, and no ulceration, and usually the liver is normal in size or slightly enlarged, and the pancreas normal.

Theories of Causation.

Various theories of origin are cited. Against that of enteritis is the absence of intestinal ulceration, and against that of pancreatic deficiency, the following facts: 1. Fat splitting may be detected in fæces, up to 80 per cent. of total fat. 2. No muscle-fibres can be found in the stools. 3. Loewi's sign is negative. 4. No changes are found in the gland at post-mortem.

As regards urinary diastase, this on April 19th, 1925, was 4 units only (the normal being 10–20 units), and again on April 2nd, 1926, one year later, 5 units. In this particular case, however, the fat estimation would suggest a pancreatic deficiency, since the great part of the total fat remained unsplit into glycerine and fatty acids.

—	September, 1923.	November, 1924.	October, 1925.	April, 1926.
	%	%	%	%
Total fat	46	23	59·64	21·37
Split fat	6	10	48·7	17·81
Unsplit fat	40	13	10·94	3·56

It will, however, be noticed that whereas in October, 1925, the majority of the fat was being split, yet the child was persistently losing weight, which is strongly suggestive that the condition was one of an inability to absorb fat, rather than of a pancreatic deficiency.

In support of his theory of a "Defective Excretion of Bile Salts," Dr. Reginald Miller[1] has declared that "cœliac disease is a digestive fault and not an organic disease. Of the glands concerned in fat digestion, the *liver* seems under chief suspicion." And again—

"We know that the disorder is not due to a persistent inhibition of the bile flow, but speaking for myself only, I think it not unlikely to be due to some abnormality in bile salts secretion. . . . I give courses of bile salts, which in many cases lead to an increased absorption of fat."

* A paper read before the Devon and Exeter Medico-Chirurgical Society.

Course and Treatment of the Case.

In this case sod. glycocholate, gr. i., t.d.s., were administered in January, 1924, without any advantage, but from February to June, 1925, Parke, Davis and Co.'s "bile salts (gr. ½) and pancreatin (gr. iii.)," with sod. bicarb. (gr. xxx.), t.d.s., apparently proved beneficial until an epidemic catarrhal jaundice threw her back materially. Unfortunately, at this time it was impossible to make any investigation of liver efficiency.

Since 1913 Rowntree, Hurwitz, and Blomfield,[2] and later Sabatim,[3] Aaron, Beck and Schneider,[4] and Piersol and Bochus[5] in America, have been advocating hepatic efficiency tests by the use of phenoltetrachlorphthalein (or bromsulphalein), salts now used in the X raying of the gall-bladder. But, unfortunately, this would have necessitated the withdrawal of 8 c.cm. of blood from the child's vein and the injection of 20 c.cm. to 30 c.cm. of diluted dye washed in with a further 25 c.cm. of saline. Assistance was therefore sought from the *lævulose test.* This showed an increase at one hour of 25 mg., which, according to Spence and Brett[6] and de Wesselow,[7] might be evidence of diminished liver function. But this rise was not sustained, nor did lævulose appear in the urine.

The patient was given breakfast at 5.30 A.M., consisting of dried toast and a poached egg, and the test was commenced at 11 A.M. on April 2nd, 1925.

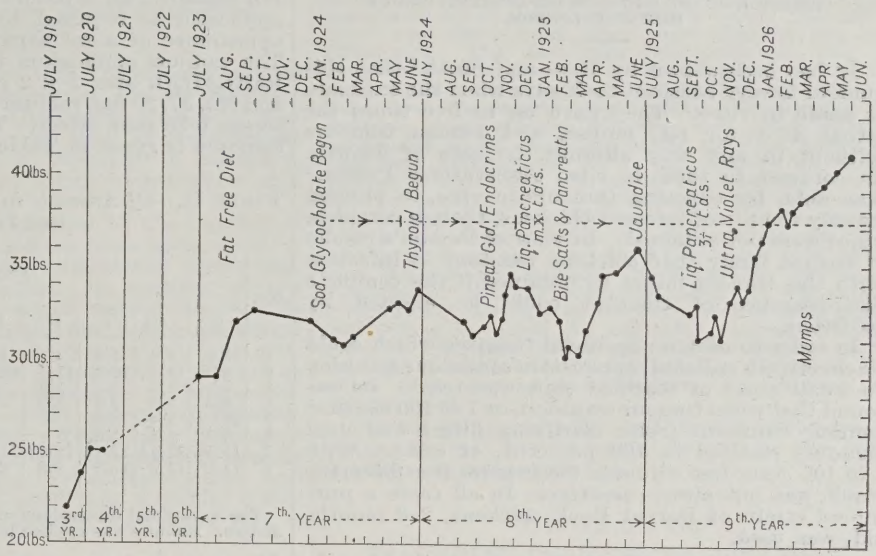
Blood.	*Urine.*
Before lævulose = 0·15 per cent.	Before lævulose—no reduction of Fehling's solution.
30 gm. lævulose given— ½ hour after = 0·137 % 1 ,, ,, = 0·175 % 1½ hours ,, = 0·153 % 2 ,, ,, = 0·146 %	No reduction of Fehling's solution in any of the specimens.

Therefore, because this lævulose test was indecisive and there was no marked improvement by giving bile salts, I personally think that the liver is not to blame. Nor is there in my opinion any endocrinal disturbance. Thyroid was harmful, and Carnrick's pineal gland comp., containing ant. pit., gr. 1/5; thyroid, gr. 1/8; adrenalin, gr. 1; ovarian, gr. 1 1/2; pineal, gr. 1/3, produced a transitory improvement but no more.

Before passing further I should like to lay stress on the capriciousness of the child's appetite. It has been written that the keynote of treatment is the diminution of the fat intake, and that thereby a wasted ailing being can be turned into a contented chubby child. But this was more easily ordered than enforced.

In December, 1923, there was severe anorexia, with refusal of all cooked meats. Again in February, 1924, she was so difficult to feed that all diet restrictions had to be withdrawn. Her tastes were for dry biscuits, greens, pickled onions, apple jam, butter and potatoes, milk and potatoes, liver and eggs, but no meat. Later in September, 1925, she would not eat "cooked" dinner, but only sausages, and 1½ pints of milk, with bread and butter. No eggs, meat, or fish. She preferred a dry biscuit. In view of this anorexia for protein, it was difficult to exclude fats entirely.

In cœliac disease there is said to be a deficiency of calcium in the blood, and tetany and late rickets may complicate it. Other observers have reported the ineffectiveness of treatment with calcium and parathyroid. Ultra-violet radiation, however, increases blood calcium. Moreover, Dr. Leonard Parsons[8] discusses the "value of irradiated cholesterol in rickets," and cites various workers and their theories for the changes produced in the cholesterol or the animal. For example, Drummond contends that the "growth vitamin" fat-soluble A is synthesised in the cholesterol, Rosenheim and Webster that the animal's own vitamin is "mobilised," and again Nelson and Steenbock that the light has increased



In the chart the words "ultra-violet rays" should align with October, 1925.

But this rise was not sustained, the antirachitic factor in the animal's tissues themselves.

Whatever occurs ultra-violet radiation was of definite value in this particular case. Treatment was commenced on Oct. 24th, 1925, from which date the child persistently gained in weight and physique. The continuation notes are appended.

24/10/25: Ultra-violet ray daily for a week, and then three times weekly under a mercury-vapour lamp.

20/11/25: Not disturbed at night for last two weeks. Bowels open, 1 per diem. Eating well (oatmeal, bread and butter, milk + +).

4/12/25: No diarrhœa or vomiting for two weeks.

8/1/26: Height, 41½ in.; body-height, 23 in.; circumference of head, 18⅞ in. No chilblains for first time. Taking cream.

14/3/26: Mumps—without set-back.

12/4/26: Urinary diastase = 5 units. Blood count = R.B.C., 5,300,000 per c.mm.; Hb, 70 per cent.; C.I., 0·7; leucocytes, 6200.

16/4/24: Height, 42½ in.; body-height, 23½ in.; circumference of head, 19 in. "She goes and helps herself to the milk." Potatoes and butter, jam + +, oranges, apples, bananas.

I think, therefore, I am justified in this case in concluding that *post hoc* is *propter hoc.* It is extremely regrettable that the blood calcium was not estimated in this case. As an explanation, however, I would submit these two theories: 1. The ultra-violet rays have proved beneficial by improving the calcium metabolism in some way, rendering the fats more readily assimilable as soap by the lacteals. 2. That the rays develop in the child's tissues a vitamin which renders the fat capable of absorption. For, whereas she refused milk in any quantity, the source of fat-soluble A, now she does not seem to be able to drink and eat enough milk and butter, of which she daily consumes three quarts and half a pound respectively.

THE EFFECT OF β RADIATION ON ROUS CHICKEN TUMOUR.

BY J. C. MOTTRAM, M.B. LOND., D.P.H.,
DIRECTOR OF THE RESEARCH DEPARTMENT, RADIUM INSTITUTE, LONDON.

IT has been shown by Russ and Scott [1] that this tumour is very resistant to X rays when the exposure is made in vitro. They gave up to five times the lethal dose for rat, mouse, and human tumours without in any way altering the rate of growth. In contrast to these in vitro observations Peyron [2] was able, by exposing tumours in vivo, to prolong greatly the life of infected chickens, though complete cures were not obtained. In view of Peyron's results it seemed likely that chickens resistant to infection with this tumour might be obtained if the complete disappearance of tumours could be effected by radiation.

In order to obtain superficial tumours which could be effectively radiated, application of tumour emulsion to small areas of scarified skin was tried. It was found that when tumour emulsion, or 1 in 100 clarified tumour emulsion (Seitz clarifying filter) was used tumours resulted in 100 per cent. of cases. With 1 in 100 germ-free emulsion (Seitz germ-free filter) the result was not always positive. In all cases a pure inbred strain of Barred Rock chickens, 2–3 months old, was used.

	60	T. E. to Sc. left side.	,,

T. E. = Tumour emulsion. Sc. = Scarified.
Disap. = Disappeared.

As a preliminary the effect of removing the tumour by operation was tried, as by this means, apart from radiation, a condition of immunity might follow the temporary growth of the tumour. It was found that the removal of a tumour by operation does not render the chicken resistant. The effect of radiating the cutaneous tumours was next tried. The results are given in Table I. It is seen that β radiation causes the disappearance of the tumours, the dose required being not much greater than that required to cause the disappearance of Jensen's rat sarcoma. For instance, an exposure of 40 minutes to the No. 4 applicator is required to cause the complete disappearance of a rat sarcoma measuring 5 × 5 mm. The radium applicators used were No. 4, 110 mg. $RaBr_2 4H_2O$, area 2 × 2 cm., screen 0·12 mm. silver and No. 57, 20 mg. radium element, area 15 × 15 mm. screen 0·35 mm. silver. The growth of the radiatep tumours is given in Table II. Apart from radiation these cutaneous tumours have not been observed to disappear; they grow rapidly, spread to the subcutaneous tissues, and lead to metastases in the viscera. These animals, in which tumours had disappeared following radiation, were rescarified twice with negative result, controls being positive in each case.

The superficial dimensions of the tumours are given in millimetres. Radium was applied in each case after the first reading.

Discussion.

The great difference in sensibility to radiation according to whether it is radiated in vitro or in vivo has not been recorded for any other tumour. The resistance to radiation in vitro is probably associated with the fact that this tumour can be propagated by cell-free filtrates. Sections of radiated tumours show that the tumour cells are destroyed in the usual manner, but why the infective agent which is presumably not destroyed by the radiation does not infect the surrounding tissues is unknown. The question as to whether after radiation in vivo the tumour loses its power to infect by a cell-free filtrate cannot as yet be answered. In these experiments three tumours were used, one from Dr. Gye and two from Dr. McIntosh, all of which gave rise to tumours with cell-free filtrates. Further, they were from time to time tested to ensure that they had not lost this property. It may thus be concluded that though a tumour in a patient be easily destroyed by β radiation, it may nevertheless be of a kind which could be propagated by a cell-free filtrate; the effect of radiation in vivo on it is no criterion.

Conclusions.

1. Rous chicken tumours capable of infecting by cell-free filtrates can be destroyed by β radiation.

2. The dose acquired is not very different from the dose required to destroy mouse and rat tumours, and is very much less than that required to destroy Rous tumour by means of X rays applied in vitro.

3. Chickens in which tumours have been made to disappear by β radiation exhibit resistance to subsequent infection.

This research was carried out under a grant made by the British Empire Cancer Campaign. Some of the radium used was on loan from the Medical Research Council.

Clinical and Laboratory Notes.

ALKALOSIS.

TREATMENT BY AMMONIUM CHLORIDE PER RECTUM AND CONCENTRATED SODIUM CHLORIDE INTRAVENOUSLY.

BY R. CHALMERS, M.D. ABERD., F.R.C.S. EDIN.,
HONORARY ASSISTANT SURGEON, GREENBANK HOSPITAL, DARLINGTON.

IN THE LANCET of Oct. 16th, 1926, in an article on Before and After Operation, by Sir Berkeley Moynihan, the subject of alkalosis is dealt with, and the treatment suggested is that of intravenous injection of normal saline, repeated if necessary, and the administration of dilute hydrochloric acid by the mouth.

The line of treatment indicated by the heading of this article is one which I have been using for over a year now in all cases of intestinal obstruction with very successful results. It consists of the administration of 3 drachms of ammonium chloride in 5 or 6 oz. of water per rectum just before operation; and of the administration of 10 oz. of a 15 per cent. solution of sodium chloride intravenously as soon as the patient is put under the anæsthetic. The stomach is, of course, always washed out previous to administration of the anæsthetic. Even after prolonged intra-abdominal manipulations the patients usually go off the table with most satisfactory pulse, and at one's visit next day a word that generally comes from their lips, on being asked how they feel, is "champion."

The rationale of the treatment appears to be that there is such a loss of HCl to the system by vomiting that the chlorides are seriously depleted, and require replenishing. This is supplied by both the salts used, but the ammonium may have some further beneficial action on the liver chemistry. As regards the use of so concentrated a solution of sodium chloride, it may be that its beneficent action is in part due to it being so concentrated, and so preventing an exosmosis of plasma salts into the intestinal tract, much the same as hypertonic saline acts so beneficially in the treatment of cholera.

The only drawbacks to this line of treatment are: (*a*) marked thirst, which, however, helps in flushing the system with plenty of fluid; (*b*) sometimes anuria may be accompanied by severe diarrhœa, but which are not of long duration; (*c*) thrombosis of vein used for the injection. This does not seem to cause any trouble.

Two recent cases, both of severe intestinal obstruction from abdominal tuberculosis, will serve to illustrate its use.

Clinical Records.

CASE 1.—Male, aged 30, admitted to hospital with pain over appendix area, vomiting, and signs of obstruction. Treatment as above given. Stomach washed out (contents being large amounts of brown offensive fluid). Operation revealed extensive abdominal tuberculosis, most marked in the ileo-cæcal region, but with adhesions involving most of the neighbouring coils. The bowel already looked purplish, and the adhesive bands in this area were sloughing. A cæcostomy was done, as the condition of the patient did not allow of anything further, and the outlook was not hopeful. Afterwards the patient's condition improved considerably, and his cæcostomy acted, while his colon was relieved by enemata. Some 10 to 14 days after, the cæcostomy refused to operate, gentle irrigation refused to bring anything away, and the patient began to complain of more pain. There was no vomiting, however, until after administering of 5 grains of calomel without its having any effect via the cæcostomy. It was decided to reopen the abdomen. After preliminary washing out of stomach, giving of ammonium chloride and concentrated sodium chloride, the abdomen was opened, and the collapsed small bowel was traced up to where another band strangled the bowel. Above this the small gut was dilated to the size of a dilated colon, was full of fluid, and quite inert. The bands were cut, the fluid milked down the gut, and a jejunostomy performed. Sterile paraffin was passed over the raw surfaces left from breaking down of adhesions. Next day the patient was in wonderful condition, his only complaint being of great thirst. The jejunostomy drained away pints of dark brown fluid for days, and was used to feed him with 0·5 per cent. sodii bicarb. solution and 5 per cent. glucose. It was some days before the cæcostomy acted again, and only after the continued use of pituitary and eserine. Thereafter convalescence was uninterrupted.

CASE 2 was that of a man, aged 25, admitted to hospital with signs of intestinal obstruction. His previous history was to the effect that he had undergone two abdominal operations for obstructive symptoms, when bands were found and enlarged glands noted. The last of these was three years ago, since when he had kept quite well. His face was very pinched, and he complained of a great deal of abdominal pain. The same routine was observed; stomach washed out, am. chlor. and concentrated NaCl given. On opening the abdomen very extensive adhesions were found all over, particularly on the right side of the abdomen, where one band was kinking the bowel very tightly. It seemed hopeless to try to deal with all the adhesions and cover all the raw surfaces left. A jejunostomy was done, sterile paraffin passed all over the raw surfaces, and a drainage-tube lodged suprapubically. The jejunostomy was to be used to wash out the upper tract four hourly with 0·5 per cent. sodii bicarb. solution. Next day the patient felt "champion," and had a splendid pulse. It was noticed, however, that each time he was washed out or had a glucose feed with sodii bicarb. he was sick, bringing up bilious material. Thinking this might be some remains of the alkalosis, I advised the use of saline and glucose, after which there was no more sickness, and progress was uninterrupted.

The use of normal saline and glucose intravenously seems to find a very useful sphere in the allied condition of intussusception.

A NOTE ON THE BACTERIAL CONTENT OF ICE-CREAM.

BY E. G. RAWLINSON, M.D. TORONTO, D.P.H. OXF.,
DIRECTOR OF PATHOLOGICAL LABORATORIES, THE ROYAL INSTITUTE OF PUBLIC HEALTH, LONDON.

THIRTY-FIVE samples of ice-cream, taken from various sources and exposed for sale in London, were examined in the hot period between July 16th and August 16th this year. The investigation was limited, and was undertaken only to obtain a general idea of bacterial contamination with reference to the number of organisms and the presence of coliform organisms, *B. enteritidis sporogenes* and streptococci.

Bacterial Count.—The number of colonies growing on agar at 37° C. for 24 hours :—

2	samples	showed	under a million per c.cm.					
6	,,	,,	between 1	and	10	million	per	c.cm.
9	,,	,,	,, 10	,,	50	,,	,,	,,
3	,,	,,	,, 50	,,	100	,,	,,	,,
10	,,	,,	,, 100	,,	1000	,,	,,	,,
5	,,	,,	over 1000 million per c.cm.					

(2 of these were uncountable in a one-millionth dilution.)

Coliform Organisms.—The minimal amount showing the presence of acid and gas in litmus bile-salt lactose broth in 24 hours at 37° C. :—

4	samples	showed	acid and gas	in	1	c.cm.
8	,,	,,	,, ,,	,,	0·01	c.cm.
9	,,	,,	,, ,,	,,	0·0001	c.cm.
2	,,	,,	,, ,,	,,	0·00001	c.cm.
11	,,	,,	,, ,,	,,	0·000001	c.cm.

1 sample showed no acid or gas in 1 c.cm. or less amount.

B. enteritidis sporogenes.—Minimal amount showing acid and torn clot in litmus milk. The ice-cream was heated to 80° C. for ten minutes and cultures grown anaerobically for three days at 37° C. :—

6	samples	gave	positive results	in	1	c.cm.
2	,,	,,	,,	,,	,, 0·1	c.cm.
6	,,	,,	,,	,,	,, 0·01	c.cm.
3	,,	,,	,,	,,	,, 0·001	c.cm.
1	sample	,,	,,	,,	,, 0·0001	c.cm.
17	samples	,,	,,	,,	,, 0·00001	c.cm.

(Dilutions were not taken higher than 1/100,000.)

Streptococci were found to be present in 1 c.cm. of 26 samples; 9 of these were of a long-chained variety.

It should be stated that the samples were put up for culture within an hour of collection, but were not transmitted in ice; but even allowing for this, the figures appear to be excessive for a food fit to be consumed. The United States Department of Agriculture Bureau gives as an average a bacterial count of 38 millions per c.cm. in the summer months.

Of this series, 33 (two being uncountable) gave an average of 969 million per c.cm. It was noted that the two samples giving the lowest counts, which were 200,000 and 600,000, were wrapped in paper, and that those with the highest were from the street barrow, where the ice-cream tub has the greatest exposure to street dust, and the large spoon is usually kept in "clean" water. Presumably the ice-creams of this series were consumed by many London children, yet no epidemic of food poisoning actually attributed to ice-cream seems to have been reported during that period; so that these ice-creams, many of them practically bacterial cultures, were eaten without any apparent ill-results from a public health point of view.

Probably none of these organisms are directly pathogenic in the healthy alimentary tract of a child of school age, or possibly children early acquire a high degree of immunity to such as *B. enteritidis sporogenes;* but it must be admitted that the chance of virulent types of organisms—e.g., a virulent type of *B. coli*—obtaining access to ice-cream is great. Similarly, organisms of the Gaertner Salmonella group, from dust and flies, &c., may possibly occur in ice-creams sold from open receptacles in the street.

It appears to be worth while considering (apart from acute food poisoning) whether or not contaminated foods taken in childhood sometimes permanently alter the normal intestinal flora so as to lead to alteration of intestinal digestion and absorption, resulting in later life in puzzling toxæmias and diatheses.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

COMBINED SECTIONS OF OTOLOGY, MEDICINE, AND NEUROLOGY.

BLOOD PRESSURE AND EAR DISEASE.

AT a meeting held on Dec. 3rd Dr. DAN MCKENZIE (Otology) took the chair, and a discussion on the relation of abnormalities of the blood pressure to diseases of the ear was opened by the reading of a paper by Sir WILLIAM MILLIGAN (Otology). The vascular supply of the internal ear, he said, formed a closed circulation, the blood being carried away by means of three veins. A study of these vascular arrangements showed that one segment of the auditory scale could be put out of action—e.g., from embolism or atheroma—without other segments being involved. The full brunt of a pathological storm was liable to occur in the cochlea or the vestibulo-canalicular systems, or both. The auditory was the most sensitive of all the cranial nerves, and hence it very readily responded to variations of arterial pressure unaccompanied by any organic lesion. There was, however, in the matter of blood pressure a wide range of normality. A patient frequently came to the aurist because of some local disturbance such as tinnitus, which might be due not to the ear but to a general circulatory upset. This symptom might result from a blood pressure either higher or lower than normal, and it was generally bilateral. But it might be due to a local organic lesion of the ear, and then would most likely be unilateral. In such cases he advocated a closer coöperation between aurist and physician. A rushing tinnitus might be the first danger-signal of high pressure. Many transient vertiginous attacks in persons with high blood pressure were due, he thought, to arterial spasm, causing labyrinthine anæmia. In the rare condition of true Ménière's disease both the static and the acoustic segments of the ear were to some extent disorganised. But there might be a vestibular symptom-complex without loss of hearing, the so-called pseudo-Ménière's disease, a term he would gladly see abolished. Attacks of the kind under discussion were frequently induced by worry and hurry, often accompanied by over-indulgence in tobacco. Repeated vertiginous attacks of labyrinthine type coming on after sudden head movements and unaccompanied by deafness were frequently the forerunners of fatal angina pectoris. Subnormal arterial pressure, such as in severe anæmia, neurasthenia, phthisis, influenza, and diphtheria might result in temporary loss of hearing, tinnitus, and vertigo, owing to venous stasis in the internal ear. Primary disease of the internal ear was comparatively rare. After excluding suppurative conditions, when the clinical symptoms suggested disease of the internal ear, a detailed examination of heart, kidneys, and intestinal tract should be made, and the blood pressure measured. Tinnitus and vertigo were, in many cases, danger warnings of organic disease in regions remote from the ear.

Dr. LEWIS A. SMITH (Medicine) said there seemed to be a large range of blood pressure which was consistent with the performance of very good work, for people with a systolic pressure of 180, or even 200, carried on very efficiently. Folk complaining of deafness did not consult the general physician, but those having vertigo frequently did. Analysing 50 cases among his own patients, with a systolic pressure of 200, he found that only 10 complained of vertigo or giddiness, though they confessed to abnormal feelings in the head. Among 20 adult people with low pressure (100 to 110 systolic) only four complained of vertigo or giddiness. Most of those who did complain of vertigo showed great differences between the systolic and the diastolic pressures. Sometimes a complex cause was at work, as in a recent case of his own, in which there were very hard arteries; 1½ oz. of strong tobacco was being smoked daily, and definite albuminuria was present. Taking 50 patients who complained of vertigo, 15 were neurasthenics, 13 had cardio-vascular troubles, 8 indulged in tobacco (notably cigarettes) to excess; gastro-intestinal cases numbered 6, in 4 the vertigo was aural in origin, in 2 there was epilepsy, and gross anæmia was present in 2. In 37 of these 50 the blood pressure was normal. Blistering over the mastoids, with bromides and luminal internally, proved helpful in relieving the vertigo.

Dr. W. J. ADIE (Neurology) took the view (partly, he said, to provoke discussion) that there was no direct relation between abnormalities of the blood pressure and ear disease. Vertigo as a symptom, apart from ear disease, could be dismissed at once, as it accompanied so many conditions. But he did not agree with the statement in a well-known text-book that tinnitus did not occur in association with central lesions. He had never seen or heard of a case in which a central lesion produced deafness. The only certain symptom of ear disease, he contended, was deafness. Patients with high blood pressure often had small strokes, from which they recovered, but these were not caused by the high pressure; they resulted from narrowing or thrombosis of cerebral vessels, as a result of associated arterial changes. There was too much readiness, he thought, to correlate the state of the blood pressure with certain symptoms. Degenerative changes in the ear might occur coincidently with sclerotic processes in other organs, or they might be secondary to arterial disease.

Discussion.

Mr. G. J. JENKINS also expressed his difficulty in arriving at a proper criterion of normal blood pressure. When the pressure of a person was very high his efficiency might be good, though his life might be in danger. The auditory and vestibular symptoms and signs might be only part of the manifestations of unusual blood pressure, whether high or low. In the case of people with arterio-sclerosis, the taking of a hot bath would often cause tinnitus, vertigo, vomiting, and headache of severe degree. It was not possible to determine whether the lesion was labyrinthine or intracranial. He did not think that even a very high systolic pressure would produce

ear symptoms; there was a class of cases in which the blood pressure was continuously high to compensate for the diseased condition of the vessels. Often there was also evidence of disease of the labyrinth. When deafness, tinnitus, and vertigo were severe, nearly always one labyrinth was more affected than the other.

Dr. J. A. RYLE spoke of the need for distinguishing between giddiness or dizziness and genuine vertigo. Of 90 of his patients with high blood pressure only 4 had genuine vertigo, with nausea, instability, and the sensation of objects revolving. Of 18 cases of real vertigo, 11 had normal or subnormal pressure, 7 had high pressure for their age. Four of these last seven had also unilateral deafness or tinnitus, which suggested the existence of local changes.

Mr. A. R. TWEEDIE thought it well to remember that, in regard to its static properties, the human ear was a degenerating apparatus, certainly compared with that of the dog; people were constantly engaged in disregarding noises which interfered with work or comfort. Vertigo did not owe its occurrence to one uniform cause; it arose from a conspiracy of causes—fatigue, vasomotor disturbance, neurasthenia, aural asymmetry.

The discussion was continued by Dr. SALISBURY SHARPE, Dr. A. ABRAHAMS, Sir JAMES DUNDAS-GRANT, Mr. E. B. BARNES, Mr. E. WATSON-WILLIAMS, and the PRESIDENT. Dr. SMITH briefly replied.

SECTION OF ORTHOPÆDICS.

AT a meeting of this Section held on Dec. 7th Dr. W. GORDON PUGH, the President, took the chair, and Mr. S. L. HIGGS opened a discussion on the treatment and results of

Fractures of the Upper End of the Femur in Adults.

Fractures of the shaft were excluded from the scope of the discussion. Most attention, said Mr. Higgs, would doubtless be given to fractures of the femoral neck, as this accident not only endangered life but was likely to lead to severe crippling Older writers considered that treatment of these cases was almost hopeless, and that non-union was inevitable unless impaction had taken place at the time of the injury. The recent literature on the treatment was mainly American and continental. Mr. Higgs felt sure that the present routine methods of treatment were very unsatisfactory. He submitted that there were five types: (1) subcapital, (2) transcervical, (3) intertrochanteric, (4) pertrochanteric, and (5) subtrochanteric. The first two were fractures of the neck proper, and therefore always passed into the joint. The subjects were mostly old people, and the accident was the result of indirect violence, but cases were seen at all ages. Usually the fracture was not comminuted, and only loosely, if at all, impacted; its manipulative reduction was fairly easy. Commonly a painful pseudarthrosis was left. The other types (3, 4, and 5) might involve the neck of the femur, but only at the base; the sufferers were generally younger people, and direct violence was the cause. Comminution was the rule, and impaction was common. Firm bony union was the usual sequel.

It was the results of treatment of the cases of fracture of the neck proper which were so unsatisfactory, continued Mr. Higgs. Among factors which predisposed to non-union were structural changes in bone associated with old age, interruption of the vascular supply, the presence of synovial fluid, lack of apposition of the fractured surfaces, and difficulty in immobilisation. In assessing the value of various methods of treatment used for this type of fracture, he gave a word of praise to Whitman's method of abduction and fixation in plaster. Extension, wide abduction, and internal rotation reduced the deformity and brought the bony surfaces into contact. The bone had united in five of his cases treated by this method.

Operations devised for treating ununited fractures of the femoral neck came, he said, under two heads: (1) those undertaken to promote union of the fracture, (2) those in which the mechanism of the joint was reconstructed. These Mr. Higgs discussed in considerable detail. His paper ended with the following general conclusions: (1) Fractures of the upper end of the femur, excluding those of the neck proper, readily united, and ordinary extension methods, as in fractures of the shaft, were satisfactory. (2) Fractures of the neck of the femur must be treated on quite different lines to get good results. It was useless to employ the usual extension methods in these cases. Wide abduction, with fixation in plaster, should be used as a routine. Most cases so treated resulted in firm union, whatever the patient's age. The additional fixation given by inserting a bone-graft might, he thought, lead to more good results, but the operation was too highly specialised to be used generally. (3) For ununited fractures of the femoral neck operative treatment was advisable if the general condition of the patient was such as to permit of it. The kind of operation would depend on the degree of absorption of the neck and the condition of the articular surfaces. Refreshing the fractured surfaces, either with or without the insertion of a bone-graft, was indicated in cases in which the restoration of the anatomy of the hip-joint was a practical proposition. In other cases reconstructive operations would restore stability to the joint and relieve the pain.

Discussion.

Mr. E. W. HEY GROVES said that surgeons were agreed on the general principles governing the treatment of these cases, but a large proportion of bad results occurred in the practice of those who were not specially interested in the treatment of fractures, or who chose to leave such cases alone, hoping either to forget them or that they would be lost sight of. Among the causes of non-union he thought that Mr. Higgs did not lay sufficient stress on interposition of the capsule. In perhaps three-fourths of the cases he had seen there was a definite interposition of fibrous tissue which, he did not doubt, was derived from the reflected portions of the capsule. Though its removal was not necessary for a functionally good union, he thought that its presence militated against rapid bony union. He agreed with all that Mr. Higgs had said about the futility of the so-called extension method, which could not be too strongly condemned. He also agreed as to the enormous superiority of the Whitman abduction plaster, but even that gave 50 per cent. of poor results. It was impossible to foresee exactly which case would result in non-union until the most favourable time for treatment had passed, and he was therefore against this method being regarded as the routine one.

Mr. Groves did not agree with Mr. Higgs about bone-graft, and bone pegs, and contended that there was no advantage in bone-grafting which was not at least equalled by pegging; grafting, moreover, meant that considerably more time was taken in the operation. Pegging, he thought, should be the routine hospital treatment of fracture of the neck of the femur. In cases of subcapital fracture, where the upper fragment was very small, it was easy, by doing an anterior arthrotomy, to expose the upper fragment and dislocate it without separating it from its soft tissue connexions, and the head could be nailed into the neck. This ensured perfect apposition and the certainty of bony union. In 15 consecutive cases there had been a smooth recovery and firm bony union. In two cases there had been poor functional results, and a tendency to ankylosis in the joint, which he thought was due to atrophy of cartilage at the head of the bone; both patients were old. At what stage should a fracture of the neck of the femur be regarded as ununited? Not until 18 months or two years had elapsed was it thought necessary to adopt a different technique. If a reasonable amount of head remained, a restoration of head and neck, perhaps by a peg, was better, in his view, than any reconstructive operations.

Mr. R. C. ELMSLIE said that one surgeon never saw more than a small number of the cases under

discussion, and it was hard to gain experience of particular methods of operation. For some years it has been his practice to put on a hip-plaster with a long plaster spica, arranging for the patient to be slung by a Balkan frame. This facilitated nursing and tended to avoid bed-sores. He put a sling on either side of the pelvic part of the plaster, and attached the slings through pulleys to counter-weights. Mr. Higgs had said little about after-treatment. After an intracapsular fracture had been treated by plaster, should a calliper splint be put on for walking? He did not use a calliper splint now, as he believed that it forced the patient to walk with an abducted hip. He gave the patient walking exercises whilst lying in bed; then he got him up between two heavy chairs and encouraged him to take the strain on the affected hip by raising the pelvis on the opposite side. The wearing of a calliper splint was particularly a hardship to old and stout people.

Sir CHARTERS SYMONDS said that in the days before X rays were available he had taken a good deal of trouble in investigating the kind of cases now being discussed, and had been able to indicate two or three signs by which an extracapsular fracture could be distinguished from an intracapsular. He suggested that in extracapsular fracture of the impacted variety it was seldom necessary to do more than use a Hodgen splint and extension. In only one case of his own had it seemed wise to disimpact a fracture, and always it required great force to undo such a fracture. He had seen great advantages from the abduction method. With regard to open operation, in 1907 a boy had been brought to hospital with a fracture, and he had cut down from the front and undone the fracture with a chisel; after the leg was put up there had been a perfect functional result. He admitted, however, that this course would not always be wise. He thought the Liston splint was only a relic so far as extracapsular fractures were concerned; he did not think he had used it once during his 30 years at Guy's Hospital.

Mr. H. A. T. FAIRBANK said that he quite agreed that the results of treatment in cases of fracture of the neck of the femur were bad, and radiologists would admit they saw only few cases in which union had occurred. He thought abduction and plaster were not used in the right way. Abduction, he thought, should be left until the last, because abduction had the effect of locking the fracture, and it interfered with reduction. Internal rotation was also very important, and it should be carried out with considerable force for a long time, particularly if a long time had elapsed since the accident. He felt sceptical about any part of the capsule being nipped between the fragments, as mentioned by Mr. Groves. The decision as to operation must be influenced by the degree of atrophy of the head, and this atrophy, he held, depended on function. If there was a sufficiently sound fibrous union, or the fragments were sufficiently hitched together, so that the inner fragment performed a function when the patient began to get about again, the inner fragment was less likely to show marked atrophy. He thought an autogenous living bone-graft preferable to a peg.

Mr. W. ROWLEY BRISTOW said the figures at a large general hospital showed that the cases of true fracture of the neck of the femur admitted numbered, in 1921 and 1922 none, in 1923 two, in 1924 four, in 1925 eight, therefore it was of little use to speak of the general practitioner having had a chance of learning how to treat these fractures. He did not find any difficulty in treatment by Whitman's method, and he showed skiagrams of a case which was successfully treated by a general practitioner. Stiffness of the knee following fixation in plaster he had found to be a real trouble. When union failed at the end of 9 to 12 months the reconstructive method of Whitman seemed well worth a trial in ordinary cases; the shock was small, and it was not difficult to do.

Mr. W. MCADAM ECCLES said that there were two distinct varieties of fracture of the neck of the femur other than the subcapital and the transverse at the neck. There were cases in which the recurrent fibres of the capsule remained intact posteriorly, so that there was marked eversion, and a distinct separation of the two fragments anteriorly. But the fragments were held together with very little longitudinal displacement. By internal rotation followed by abduction and fixation, it was usually possible to ensure bony union. He questioned whether it was necessary to put the plaster as low down as below the knee. If it was put on the lower fourth of the femur passive movement of the knee was possible, and active movement later. When there was longitudinal deformity of the so-called intracapsular fracture a very serious condition resulted, and now that technique had improved he was coming to the view that this type of case would have to be treated by operation. He agreed with Mr. Groves that it was better to open a joint and see where the bone-graft or peg was going, rather than trust to the guidance afforded by X rays.

Mr. E. M. COWELL referred to the ambulance authorities' first-aid regulations requiring that these cases should be treated by extension and a Thomas splint immediately after the accident. After this the patient could be conveyed more comfortably to hospital, where he often arrived suffering very little pain.

Mr. A. H. TODD stated his opinion that the most important cause of failure to unite was lack of apposition of fragments. Reliance on a single antero-posterior radiogram of the region was a cause of much misinterpretation and therefore of mistaken treatment. The actual position of fragments in relation to each other could only be judged by stereoscopic pictures. Radiology must be regarded as an integral part of the first examination of a case. A surprising number of medical men felt they could be sure whether or not a fracture had united by a mere inspection of the radiogram. There was a good deal of erroneous teaching in regard to fractures of the neck of the femur. He used to be taught that the absorption taking place after fracture of the neck of the femur was principally that of upper fragments, whereas the absorption was in the neck, not in the head. It was now known that faulty treatment of these cases was the direct result of wrong tuition.

MANCHESTER MEDICO-CHIRURGICAL AND OBSTETRICAL SOCIETY.

A MEETING of this Society was held on Nov. 17th, when Mr. A. C. MAGIAN read a paper on

Insufflation of the Fallopian Tubes.

The method, he said, had been originally introduced by Rubin and afterwards simplified by Bonney and others. Rubin's figures for 1000 cases of sterility indicated that about 9 per cent. had been cured, but his own results had not been so good, partly, perhaps, because the cases had been more carefully selected. After many years of sterility a woman might have a child without any intervention; furthermore, the mere fact that the patient was under treatment for sterility might affect the intercourse of husband and wife. The information given to the gynæcologist was often inaccurate, and taking all these things into consideration he doubted whether insufflation could cure sterility in more than 2 per cent. of cases; in general the percentage was probably much lower. Cure could only occur where there was no more than a very fine obstruction in the Fallopian tubes. Insufflation would break down cobwebby adhesions and straighten out a slightly distorted canal, but that was all it could do with safety.

There was a good deal more to be said, continued Mr. Magian, for the use of insufflation in diagnosis, for with average skill and care it was possible to diagnose obstruction in the Fallopian tubes in a very large proportion of cases. It must only be used, of course, where no obvious or gross lesion could be

detected. The surgeon would not employ such a method if he suspected a pyosalpinx, for example, nor when there was the slightest doubt as to the presence of active gonorrhœa, nor when any form of sepsis could be discovered. Without due care septic particles might be blown right into the abdominal cavity with disastrous results. The vagina should be washed out twice daily for a few days, and just before insufflation it was well to paint the vagina and cervix with tincture of iodine. Precautions must be taken as for a major operation. Rubin had done his examinations without an anæsthetic, but this was inadvisable for the ordinary practitioner, as the operation might cause severe shock. Under open ether the cervix was dilated up to No. 10 Hegar, and a hollow sound was passed right into the uterine cavity, so that the internal os could grasp it tightly. The apparatus was also connected with a manometer, which accurately registered the pressure. Under ordinary conditions a pressure of 100 mm. would suffice to blow air through the patent extremities of the Fallopian tubes, but where there was obstruction a pressure of over 200 mm. might be needed; it was unsafe to go much further than this, and it was certainly risky to reach 250 mm. During insufflation the observer listened the whole time with a wide-mouthed stethoscope over the iliac regions for the faint rustling sound which showed that air was escaping through the fimbriated extremities of the Fallopian tubes. If one tube was obstructed, air would only be heard escaping on the other side, and the manometer would probably register at least 150 mm. If the manometer first registered, say, 200 mm. and then suddenly the pressure shot back to 100 mm., it was probable that there had been some slight obstruction in one or other of the tubes which had been broken down by the increased pressure. Where the tubes were diseased—e.g., pyosalpinx or hydrosalpinx—the air pressure in itself might, of course, burst the tube and cause peritonitis. By injecting a thick solution of barium or lipiodol into the uterus and then taking an X ray photograph, it was possible in a fair number of cases to determine the exact position of the obstruction. With obstruction at the isthmus there was not much chance of recovery by operation or otherwise, but if the block was at the fimbriated extremity it was quite likely that the condition could be cured. If it was in the middle of the tube, there was the possibility of making a new and efficient ostium. The injection of the emulsion was always difficult, and results obtained on the X ray plate were often rather unsatisfactory.

Dr. P. M. MILLIARD asked if insufflation could suitably be performed in the surgery of a general practitioner.

Dr. E. C. DUTTON inquired if the injection of lipiodol into the uterus was a safe procedure, and if the results were worth the trouble.

Dr. MURIEL KEYES asked what percentage of patients whose sterility was diagnosed as due to tubal occlusion afterwards consented to operation.

Mr. MAGIAN, in reply, said that he thought it best not to undertake tubal insufflation except in a hospital or nursing home. The patient should remain in bed for 24 hours after the operation. There was sometimes complaint of a little discomfort, and in all cases the anæsthetic caused a certain amount of sickness. The injection of lipiodal might be considered quite safe under the same conditions, but the results of any X ray work were generally unsatisfactory unless the operator was an expert. Most patients who were keen enough to have tubal insufflation done would go on with the treatment afterwards suggested. In answer to a question as to the danger of the practitioner being imposed upon by an unscrupulous woman who concealed a suspicion that she was pregnant, it was necessary for him to be always on his guard. This was an additional reason for the treatment being done in a public institution or in a nursing home with the coöperation of a colleague or assistant.

Reviews and Notices of Books.

WHY TUBERCULOSIS EXISTS.

How it may be and has been Cured and Prevented. A Book of Facts. By R. GOULBURN LOVELL. London: John Bale, Sons and Danielsson. 1926. Pp. 211. 6*s*.

THIS work is compiled from various sources by Mr. R. Goulburn Lovell, a retired English architect, who is an old family friend of Mr. Henry Spahlinger, and has been closely associated with him in his work since 1912. The reason why tuberculosis exists is, in the opinion of Mr. Lovell, first and foremost because the Spahlinger methods have not been adequately applied to the treatment of the disease. The book contains a large number of letters and reports as well as extracts from the lay press, and there is a good deal of repetition in consequence. For purposes of review it may conveniently be regarded as consisting of two sections, one dealing with the medical and scientific facts available on the subject of Mr. Spahlinger's work, the other with the struggle for official recognition and financial backing.

The treatment consists of two separate and distinct methods of immunisation—active and passive. The technique of preparation of antigen and antiserum is not given here in sufficient detail to enable workers in other laboratories to carry it out. As regards the antigen, the tubercle bacillus is "separated into its component parts," and from these are prepared "separate antigenic solutions which are injected in successive doses" until finally the patient can tolerate "the whole organism of the bacillus." From separate toxins identified and isolated the antisera are manufactured. "Each toxin is injected into one or more horses. . . . No two toxins are injected into the same animal, and for preparing the complete serum not fewer than 28 horses are needed. . . . When this process has been continued for perhaps 12 months, the horses are painlessly bled. The 28 partial sera thus obtained are combined, and the serum, now complete, is put up into ampoules ready for use." Of these partial sera only seven are in existence at the present time. "The possibilities of a cure with these partial remedies are variable. It may be that with one patient a certain combination of the partial sera—if the right ones are to be had when needed—will be enough to turn the scale and effect a recovery. Another patient may need another combination of partial sera, and so on." To these tubercle antitoxins appear to be added the antitoxins of streptococci, staphylococci, and pneumococci.[1] No details of standardisation of any of these numerous toxins and antitoxins are given. On the therapeutic side the book contains records of guinea-pig experiments, bovine immunisation, and human patients. Between December, 1911, and March, 1912, a first series of five tuberculous (human strain) guinea-pigs were treated. In January, 1913, these animals were killed, and found to be free from tubercle bacilli when smears were made from the organs, whilst emulsions of inguinal and lumbar glands failed to infect eight fresh guinea-pigs (Prof. Letulle's report). Meanwhile a fresh series of 17 animals had been started. Seventeen infected guinea-pigs were treated from April to July, 1912. "In July of the same year 15 of them were completely cured; the other two survived for six months and then died." Controls were also made (Dr. Lardy's report). It is unfortunate that no more precise details of these experiments upon which a bacteriologist could assess their value are given. They are exceptionally important experiments, and we regret that Mr. Spahlinger has not repeated them or enabled others to do so.

The statistics of the bovine experiments are vague. In 1916 "some 20 cows" were immunised by Mr. Spahlinger with his vaccine. Six months after

[1] Vide Report of Chief Medical Officer of Ministry of Health, 1922. H.M. Stationery Office.

immunisation the animals were inoculated with living tubercle bacilli previously proved to be virulent for other animals. Since 1917 "several of these cows" have again been inoculated with living tubercle bacilli of ascertained virulence, but none of them became infected. In 1918 "some of these cows" were killed and examined, but no lesions of tuberculosis were discovered post mortem. The report concludes with the statement that "all the cows" vaccinated in 1916 were tested with tuberculin in 1923 with negative results, and were alive and well in 1924. Presumably the words "all the cows" mean all not killed in 1918. (Fifth British Investigation, 1924.)

The record of the human cases treated covers many pages, and space only permits of a very brief summary. In March, 1926, the Lancashire and Cheshire Branch of the British Medical Association collected in five schedules 489 known cases treated, with an average of 74 per cent., stated to be recoveries during 14 years, and 90 per cent., stated to be definite responses during the past year. These records include surgical cases and cases of pulmonary tuberculosis with or without tubercle bacilli in the sputum, some of them having complications such as laryngitis, enteritis, others being evidently relatively slight cases. It is impossible to analyse them, but the results of the cases with tubercle bacilli present may be quoted from the summaries of the five schedules :—

A. 1912–14 ..	42 cases	..	78 per cent.	recoveries.
B. 1915–20 ..	38 ,,	..	78 ,,	,,
C. 1915–20 ..	265 ,,	..	70 ,,	,,
D. 1921–24 ..	33 ,,	..	43 ,,	,,
E. 1925–26 ..	38 ,,	..	87 ,,	responding.

The low percentage of recoveries in the cases of schedule D is considered to be due to the few sera which were available. In these records, as in others dealing with new tuberculosis remedies, there appear to be very few cases of lupus. Incidentally, at the long last when a cure for tuberculosis is fully established, it is not unlikely that the cases of lupus will provide the acid test.

Only the bald facts have been given to the outside world, the rest remaining now, as in 1912, Mr. Spahlinger's secret. The statement made by the Lancashire and Cheshire Branch of the B.M.A. and quoted on p. 32 of this book that a full exposition of the methods were given in THE LANCET of Jan. 7th, 1922, is not correct in the sense that the exposition is sufficiently explicit to enable others to repeat his work. Mr. Lovell admits that something vital has been withheld, for he defends Mr. Spahlinger's attitude in this respect, quoting Ehrlich's action with regard to salvarsan in support thereof. There are, of course, numerous other instances where important details of a new discovery in medicine have been kept secret until the value of the work has become assured. Allowance must be made for the fear of exploitation; Mr. Lovell quotes at least one instance in which exploitation of Mr. Spahlinger by a commercial firm has been attempted. But in spite of these considerations and without in any way impugning Mr. Spahlinger's good faith, we believe he has made an error of judgment in not taking the medical profession fully into his confidence. This might have been done, for instance, through a select committee of trusted bacteriologists, a method which has been adopted in the past.

The efforts of Mr. Spahlinger's helpers to obtain official recognition and financial backing make a long story of difficulties, misunderstandings, and recriminations. We do not consider it necessary to discuss the prolonged negotiations here recorded by Mr. Lovell, not always in the most charitable terms, with various public bodies in Britain. Briefly stated, the position appears to be that the supply of complete antisera and vaccines has been exhausted for some years, that the preparation of small quantities of partial serum has, however, been carried on, that the production of the complete antisera on a large scale would take three or four years, and that financial provisions for such manufacture cannot be made. The Ministry of Health has agreed to make a test investigation when an adequate supply is forthcoming, but considers that it has no statutory right to permit the Insurance Committee or the approved societies, from whom it was hoped to obtain substantial donations, to allocate funds for the preparation of the remedies. "At present," writes Mr. Lovell, "only those privileged patients whose friends can make substantial donations—free and unconditional—can hope to benefit from the treatment in Geneva, and only then if it be thought that the partial remedies in existence are likely to effect recoveries."

Now that Mr. Lovell, who is fully in the confidence of Mr. Spahlinger, has published this book, we trust that there will be an end of the sensational press notices which have appeared from time to time, and which in the long run merely serve to discourage anxious patients. We are sorry that certain portions of the book should have been written in such a polemic vein. Sections headed A Travesty of Truth, Helpers and Hinderers, and those criticising the principal medical officer of the Welsh National Memorial Association do not really help the cause in medical circles, but merely disgust those who are anxious to reach scientific truth.

LOCAL ANÆSTHESIA IN OTO-LARYNGOLOGY AND RHINOLOGY.

By JAMES JOSEPH KING, A.B., M.D., Assistant Surgeon in Otology, New York Eye and Ear Infirmary. With Supplement on the Toxic Effects of Local Anæsthetics, edited by EMIL MAYER, M.D. Preface by ROBERT A. HATCHER, M.D. New York: Paul B. Hoeber. 1926. Pp. 205. $5.00.

AFTER an interesting historical summary, the first part of this book is devoted to general considerations and a short exposition of the chemistry and action of cocaine, novocaine or procaine, as the American-produced drug is named, and of epinephrin; of the other similar synthetic compounds, butyn and apothesine alone receive mention. Butyn is condemned for its toxicity, and apothesine for its irritating qualities; the quinine-urea combination is also described as irritating. The author's views accord with the reports of the American Medical Association, except that the last-named body condemns the inhalation of ether as an antidote to cocaine poisoning which Dr. King recommends. An interesting subject discussed is the "synergistic" action of morphine, magnesium sulphate and novocaine. The author has found this combination of great value as a preliminary to operation; 2 c.cm. of a 50 per cent. solution of magnesium sulphate containing 2·5 per cent. of novocaine and ⅛ gr. of morphine is injected intramuscularly and repeated three times at half-hourly intervals, the last dose being given half an hour before removal to the operating table. For submucous resection of the septum, the author's method is to give a preliminary injection of scopolamine hydrobromide, gr. 1/150, to paint the mucosa twice with two or three drops of a 20 per cent. solution of cocaine, then with a 1 in 1000 solution of suprarenin, and finally to inject submucously 8 to 10 c.cm. of normal saline containing 5 minims of 1 in 1000 suprarenin solution. He mentions, as Braun's technique, infiltration of the septum with 2 per cent. novocaine-suprarenin solution, but does not give the quantity to be used nor the concentration of the latter drug; apparently he does not use this technique himself, though he says that "the method is sound and may, in time, supplant the use of the more toxic cocaine."

Dr. King has not attempted to provide us with a manual of the technique of local anæsthesia in its application to the surgery of the nose, throat, and ear. The chapters dealing with technique occupy but 36 pages; and these include four half-page illustrations of the after-results of tonsillectomy, which have no real bearing on the subject. This part of the book must be described as perfunctory.

Exactly one half of the book is occupied by the three reports of the committee of the American Medical Association edited by Dr. Emil Mayer. These are not dated, but the first appears to have been issued in 1920, and the third in 1924; this final report has, at any rate, been published before, and was noticed in THE LANCET of May 17th, 1924. The most important recommendations of the Association are that cocaine should not be used by injection, and that cocaine paste or "mud" should be unreservedly condemned. The committee lays down a list of concentrations of local anæsthetics which they believe may be safely applied; for instance, cocaine in the nose not over 10 per cent. and in total amounts of 10 to 15 minims; we think that they do not here take sufficient account of idiosyncrasy, for undoubtedly people do exist who are dangerously affected by a much smaller dose of the drug than this. In this connexion we may quote the account given of a patient's death during tonsillectomy: he had received 2 drachms of a 0·5 per cent. novocaine solution with one drop of 1–1000 adrenalin; he had hypertension and nephritis, but was considered a safe risk; the editor's comment is that "in the opinion of the writer the drug may only be considered as a contributing cause at the most."

The committee collected 43 cases of death by (or under) local anæsthetics, and consider that such accidents are more frequent than is commonly supposed; they point out that death is too commonly due to mistake, such as the unintentional injection of cocaine instead of novocaine, and they insist that the quantities used even in surface applications should be accurately measured.

THE BACTERIOPHAGE AND ITS BEHAVIOUR.

By F. d'HERELLE, M.D., Directeur du Service Bactériologique du Conseil Sanitaire, Maritime et Quarantenaire d'Egypte. Translated in English by GEORGE H. SMITH, Associate Professor of Bacteriology and Immunology, School of Medicine, Yale University. London: Baillière, Tindall and Cox. 1926. Pp. 629. 36*s*.

THIS book contains a complete re-statement of the facts and theories concerning the bacteriophage, and is not merely an enlarged edition of the author's previously published monograph. The amount of work which has been done in this field in the interval which has elapsed since that work appeared in 1921 is shown by the fact that, whilst the original monograph made reference to 88 papers upon the subject, the present book contains 647 references. Dr. d'Herelle has done well in not attempting to incorporate this enormous mass of literature within the framework of his previous publication; he has produced what is, in title and material, an entirely new work.

The subject matter falls into three portions. The largest deals with the phenomenon of bacteriophagy, the technique of its investigation, and the conditions of its occurrence. The second portion deals with the physical properties of the bacteriophage and the evidences and speculations as to its nature. Here we find the author firmly upholding his original contention of the living parasitic nature of the creature, for which he now coins the term "protobe," which, he states, must be understood to designate a protein particle of the smallest possible colloidal dimensions; the dimensions of the bacteriophage are given as about 20 $\mu\mu$ in diameter. Thus, d'Herelle has shifted his grounds considerably since his earlier publication. He then stated that the lysis of organisms by the bacteriophage must in the last resort be due to a soluble enzyme which should be separable from the bacteriophage. He claimed to have demonstrated this experimentally and to have produced a solution of the enzyme capable of causing the phenomena of bacteriolysis which was in this case not serially transmissible. This is the point which has been seized upon repeatedly by opponents of his view, who have maintained the impossibility of obtaining the same results. In the present book he abandons this standpoint, and remarks that such an experiment might be due to a lytic product, either of the bacteriophage or one set free from the dissolved bacteria. The third section is devoted to the use of the bacteriophage in treatment and its significance in epidemics, in which he stoutly maintains that resistance is a question of bacteriophagic activity. It is upon these points that one would like to see some systematic experiments made in this country for the writer's claims are not modest, while up to this point, upon which others have been in the main silent, they have generally proved fairly well founded.

GLIOMA TUMOURS.

A Classification of the Tumours of the Glioma Group on a Histogenetic Basis. With a Correlated Study of Prognosis. By PERCIVAL BAILEY and HARVEY CUSHING. London: J. B. Lippincott Company. 1926. With 106 illustrations. Pp. 175. 21*s*.

IN recent years important developments in histological technique have emanated from the Spanish schools (Cajal, Castro, Rio Hortega, and others), and have resulted in a much more discriminating investigation of neural elements than has hitherto been possible. The results are seen, as far as one branch of study is concerned, in this finely illustrated book on tumours belonging to the glioma class. Older classifications go by the board altogether when the student realises that the authors now distinguish no less than 14 varieties of glioma. Nor is this a mere refinement of histological methods; the distinctions have a clinical as well as a purely technical interest. It has been the endeavour of the authors to trace all cases operated on, since they have been impressed by the fact that in not a few instances of incomplete removal of a glioma the period of survival has been unexpectedly long. They have discovered that the tumours whose cells reproduce the structure of the less differentiated cells in the developing central nervous system belong to an actively growing class much more so than the tumours composed of cells that are more highly differentiated. Hence the importance for prognosis; almost half of the glioma group consists of varieties of tumour which may be regarded as comparatively benign.

THE BASAL GANGLIA AND THE EXTRAPYRAMIDAL MOTOR SYNDROME.

Die Stammganglien und die extrapyramidal-motorischen Syndrome. By F. LOTMAR, privatdozent in the University of Berne. Berlin: Julius Springer. 1926. Pp. 169. M.13.50.

THE output of monographs dealing with the basal ganglia and extrapyramidal disease shows no signs of abating. Nor, unfortunately, is there much evidence in the present instance of any critical combing of so-called striatal syndromes. The conception of the corpus striatum as a convenient resting place for otherwise homeless syndromes and symptoms has received so long a start that it is doubtful whether it will ever be overtaken. Dr. Lotmar includes in his discussion of clinical conditions based on extrapyramidal disease chorea, athetosis, tremor, torsion-spasm, torticollis, tics, "psychomotor" hyperkineses, iteration, palilalia, tonic innervation (Zwangsgreifen), involuntary or spasmodic laughing and crying, and others still, altogether apart from the very numerous vegetative symptoms or symptom-complexes which he specifies. It is frankly impossible to assign all of this conglomerate to the corpus striatum, or possible only at the expense of completely ignoring those contributions by various neurologists at home and abroad which go to prove a quite other localisation for some at least of them. With the author's remark in a footnote, that we are far removed from any unanimity of hypothesis notwithstanding the many important contributions that have been made, we can, however, cordially agree.

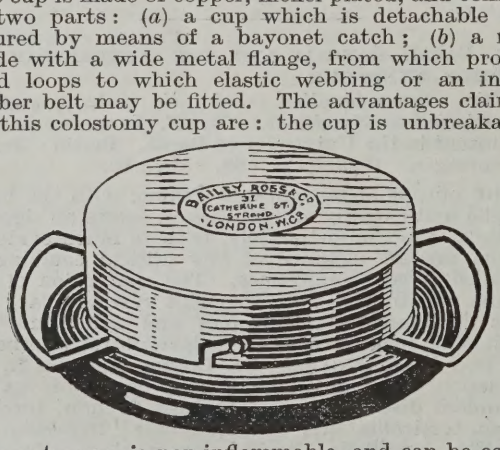
JOURNALS.

Bolletino della Società fra i Cultori delle Scienze Mediche è Naturali in Cagliari. New Series, No. 1, June, 1926.—After an interruption of several years these bulletins have been resumed under the direction of the President, Prof. Carlo Ceni, with Prof. Vanzetti and Prof. Frontali as Vice-Presidents. The first number of the new series contains an address by Prof. Vanzetti reviewing the advances made of late years in biochemistry and biology, culminating in the establishment of three facts: (1) the atom is a labile collection; (2) there exist different elements with the same atomic weight and identical elements with different atomic weight (isotopes); (3) the atomic weights of all the elements are expressed in integral numbers which are practically exact multiples of that of hydrogen. He sees that even the apparently more simple processes of cellular metabolism, the digestion of the proteins, the utilisation of the amino-acids, the chemical mechanism of muscular contraction, the phenomena of fatigue, and the more ordinary pathological changes, are to be found in colloidal systems, apparently simple, but in reality very complicated, in which we are only allowed to perceive a struggle between the individual who tends to defend and maintain the intricate texture of physicochemical equilibrium against the manifold external causes of disturbance. There are three original communications by A. Clementi: on the effects of flocculation of the biliary acids on lactic fermentation, the action of eosin on the central nervous system, and on comparative research with the *B. abortus* and *M. melitensis*. We offer our good wishes for the success of this society and its bulletins.

New Inventions.

A SIMPLIFIED COLOSTOMY CUP.

THERE recently appeared in the *Journal of the American Medical Association* an account of a colostomy belt with an improved colostomy cup. The illustration here given shows a cup made somewhat after the same plan, but simplified to suit the needs of hospitals, nursing homes, and hospital out-patients. The cup is made of copper, nickel-plated, and consists of two parts: (*a*) a cup which is detachable and secured by means of a bayonet catch; (*b*) a rim, made with a wide metal flange, from which project rigid loops to which elastic webbing or an india-rubber belt may be fitted. The advantages claimed for this colostomy cup are: the cup is unbreakable,



does not warp, is non-inflammable, and can be easily and effectively sterilised by boiling, while it is roomy enough to be lightly lined by toilet paper or gauze, and can be removed and cleansed easily. The flange is wide and rigid, and fits well on to the surface of the abdomen. It is best used without any pad, but an indiarubber pad or a layer of gamgee tissue can be worn with it if desired. The appliance is easily kept in place by a piece of elastic webbing with a perineal band. This can be home-made and fastened with hooks and removed for cleaning. The cups can be kept in stock at hospitals and other institutions, and it is not necessary to have a specially made belt for patients with temporary colostomy.

Messrs. Bailey, Ross and Co., 31, Catherine-street, Strand, London, the makers, stock the cups in the following sizes: depth, $1\frac{1}{4}$″ and $1\frac{1}{2}$″; inside diameter, 2″, $2\frac{1}{2}$″, and 3″.

GEORGE F. STEBBING, M.B., B.S. Lond.

Reports and Analytical Records.

LOBELIN "INGELHEIM."

(CHAS. ZIMMERMANN AND CO., 9 AND 10, ST. MARY-AT-HILL, LONDON, E.C. 3.)

THE dried extract of *Lobelia inflata*, official in the pharmacopœias of Belgium and the United States of America, has long been used as an anti-asthmatic and expectorant. In 1918 Prof. Wieland, of Heidelberg, isolated the alkaloid known as lobeline, of which the hydrochloride is put up in the preparation now supplied. Lobeline is claimed to be a specific stimulant of the respiratory centre without simultaneous action upon the neighbouring vomiting centre; it is stated that one hundred times the physiological dose has been administered without inducing vomiting. Clinical experience is adduced from German and Austrian sources to suggest that a dose of lobeline has succeeded where other remedies have failed in restoring regular breathing after an over-dose of morphia and in relieving the dyspnœa of pneumonia attended with cyanosis. Its employment is suggested in CO poisoning. The stimulating action of the drug on the depressed respiratory centre of mice has been recently (séance, 9th July, 1926) demonstrated at the Strasbourg Institute of Experimental Medicine and further work in the Physiological Laboratory of the Middlesex Hospital Medical School is set out in our own columns this week. A communication on the subject was made to the Section of Therapeutics and Pharmacology, Royal Society of Medicine, on Tuesday last. Lobelin "Ingelheim" is put up in ampoules containing for children 1/20 gr. (0·003 g.), for adults 3/20 gr. (0·01 g.) to be given subcutaneously, and boxes are supplied containing 2, 6, or 30 ampoules.

VAN HOUTEN'S PURE SOLUBLE COCOA.

(VAN HOUTEN LTD., COCOA HOUSE, 15 AND 17 FINSBURY-SQUARE, LONDON, E.C. 1.)

The contents of the package (which is guaranteed to contain pure soluble cocoa of the finest quality and full weight) weighed $\frac{1}{2}$ oz. over the $\frac{1}{2}$ lb. net weight claimed on the tin. When analysed this cocoa gave the following results:—

Moisture	5·64 per cent
Fat (cocoa butter)	26·50 „
Total mineral matter	6·66 „
Water-soluble ash	5·54 „
Ash insoluble in hydrochloric acid	Nil.
Alkalinity of water-soluble ash as potash (K_2O)	2·63 per cent
Protein	19·7 „
Calorie value per lb.	1250

The small proportion of alkali employed in its manufacture confers on it the useful property of remaining in suspension in the liquid and thus preventing the formation of a sediment on the bottom of the cup. The flavour is delicious, while the extreme fineness of the grinding prevents any trace of grittiness in the mouth. There is no evidence of the addition of either starch or finely comminuted cocoa shell. This cocoa is an excellent specimen of its class and maintains the high character we found it to possess when examined in our laboratories over 20 years ago.

"DIPLOMA" CRUSTLESS CHEESES.

The report on the crustless Cheddar and Cheshire cheeses produced by the Wilts United Dairies, Ltd., which appeared in our issue of Nov. 27th (p. 1118) failed to mention specifically the brand name of these cheeses—"Diploma."

THE LANCET.

LONDON: SATURDAY, DECEMBER 18, 1926.

THE PANEL DOCTOR'S GRIEVANCE.

IN the face of professional dissatisfaction with the disciplinary machinery of the National Health Insurance Act the Ministry of Health still stands stiffly upon its dignity. At a conference between its representatives and the Insurance Acts Committee, held on Nov. 30th, no definite concession was announced, or even foreshadowed. It is well known that panel doctors have always felt a certain disappointment at the absence of a right of appeal to the High Court. The practitioner enjoys at present, it is true, a right of appeal; but it is an appeal to the Ministry, and it is heard by officers of the Ministry. In this country it is admittedly a principle of law not only that justice should be done, but also that it should seem to be done; a tribunal should convince litigants of its disinterestedness; it should hear all evidence in open court, should allow every accused person an opportunity of making his defence, and should assign reasons for its decisions. While nobody suggests that the Ministry is corrupt or partial, the fact remains that its function in the disciplinary machinery of the national health insurance system fails to fulfil these requirements. Let us see how that system works. If a complaint is made against a panel doctor, a committee is assembled to hold an inquiry. The committee is a competent body, specially equipped for its purpose; it examines witnesses in the presence of the person whose conduct has been called in question; it allows him his natural right of making his defence to a specific charge. The object of the committee is to reach findings of fact which are tantamount to a verdict of "guilty" or "not guilty"; the effect of the verdict is either to exculpate the practitioner against whom the charge is made or to convict him and to assess the measure of blame and punishment appropriate to the case. The committee has no power to pass sentence, but its duty is to make recommendations. Up to this point the machinery has operated without complaint, but from this point onward its working may be open to grave criticism.

Let us suppose that the committee recommends that no penal action be taken against the person whose conduct has been the subject of its inquiry. At this stage that person has a right of appeal to the Minister, but, even if he feels dissatisfied with the committee's findings in points of detail, it naturally may not occur to him to exercise his right of appeal against a decision which is substantially favourable. The traditions of English procedure would hardly suggest that an acquittal at the police-court should be followed by conviction and punishment at the assizes. Yet that strange sequence of events is not unlike what may happen to the panel doctor in the situation already described. The officers of the Ministry, sitting *in camera*, re-hearing the case without either seeing the witnesses or calling upon the defendant, may announce an adverse decision. The committee's recommendation may be set aside and a smart fine inflicted, while, for all that the victim knows to the contrary, the grounds of this new decision may be the merest caprice, unrelated either to the original charge or to the evidence previously given. It is small wonder that panel doctors are disquieted by such incidents or that other practitioners display reluctance to expose themselves to the risk of such treatment.

The answer of the Ministry is that the inviolable mysteries of the British constitution forbid the Minister to part with his sacred responsibility. As we have already observed in this connexion before, there is another and much more important principle of constitutional law at stake—namely, the usurpation of judicial functions by executive authorities. "There is a growing tendency of Government departments and Government officials," said Lord Justice FARWELL some years ago, "to claim the right to act without regard to legal principles and without appeal to any court." This opinion does not stand alone. Sir FREDERICK POLLOCK has written weightily of the ever-increasing propensity, "constitutional traditions and safeguards notwithstanding," to confer more and more discretion of a substantially judicial kind upon officials of the great Departments of State. Finally, only a few days ago, when addressing the Birmingham Law Students' Society, of which he is this year president, the Lord Chief Justice commented upon this aspect of "the great and growing pretensions of the bureaucracy." It was becoming common, complained Lord HEWART to find in Acts of Parliament a clause to the effect that in matters of dispute the decision of the Minister should be final and binding and conclusive for all parties. If the national health insurance disciplinary machinery raises any issue of constitutional principle, it would appear that our foremost jurists will be found on the side of the panel doctors, not on that of the Ministry of Health.

THE ECONOMIC BASIS OF THE NURSE'S TRAINING.

THE glamour of nursing as a vocation for educated young women has passed away, with other enthusiasms regenerated by a state of war. Indeed, the revival of interest in this calling, which followed the release from military service of many zealous and competent V.A.D.'s, was short-lived. Most of the women who were to be dependent on their earnings examined the conditions of work and leisure and the ultimate prospects of the nursing profession and reluctantly decided against its adoption on sober economic grounds. Others, more favourably placed, were able to contemplate a life of service to the sick without fear of indigence in old age, but, having some experience of the strain of ward work shrank from the conditions involved in training, and took up medicine instead. The result was for a time to flood the market with medical women, while the hospitals still cry out in vain for probationers of the right type. The reason is largely that the student nurse, whatever her circumstances, has no option but to pay for the whole of her training in arduous service, whereas the medical student is allowed to contribute some £250 towards education, the balance being met not by her labour but by endowments and State grants to the schools. Moreover, the probationer's service is so necessary to the hospitals that she is offered in return not only tuition but payment in money and in kind, and this very fact may imply the paradox that she is buying her experience at too great a price. Practical work is, of course, indispensable in the study of both branches of the healing profession; but, ideally, its limits should be set not, as in nursing, by the amount of hospital work that has to be done by somebody, but, as in the curriculum of the medical student, by the amount that he or she can do without getting too tired to benefit from demonstrations and

theoretical instruction. In short, the time to give ungrudging service to the sick is when the student is fully qualified; to exact such service before is to blunt a weapon that is not yet tempered.

It is admittedly difficult to do good educational work in institutions which exist primarily for another purpose—the care of the sick poor. The medical schools, being financially independent of the hospitals, do not find the difficulties insuperable, but the training schools for nurses are in a less fortunate position. Under present conditions a shortage of recruits in any year is likely to involve extra work for those who have already enlisted, since these form the chief labour-supply of the voluntary hospitals. The hospitals are always pressed for funds and the extra cost of maintaining a larger staff of qualified nurses and domestic helpers to supplement the supply of workers would not willingly be borne by them. Miss MARY A. NUTTING, in the first of a series of essays bound together under the title A Sound Economic Basis for Schools of Nursing,[1] finds a remedy for the baffling problems arising out of the interdependence of hospitals and student nurses in the separate endowment of training schools. Possible sources of funds would be grants from public authorities, private benefactions and even, under the altered conditions of training that would ensue, fees chargeable to students, scholarships and loans being available for those without private means. Among the direct benefits to be anticipated would be the maintenance of a body of trained experts to give the oretical instruction and practical teaching, and the provision of adequate class-rooms, equipment for teaching, libraries, and recreation-rooms. Indirectly, by subsidising a larger hospital staff, shorter hours for students might be secured, with longer vacations and less night duty. It is clear that endowments and grants to training schools are desirable and that the recruiting of educated women to the profession would be greatly stimulated by the changes they would bring about. The possible secondary effects, which would be less acceptable in many quarters, would be to hasten the recognition of the need for grading nurses, as proposed in the report of the Rockefeller Committee on Nursing Education,[2] and to raise still further the market value of domestic servants. But since the realisation of Miss NUTTING'S ideals are at present still remote, it behoves us to examine less drastic suggestions for improving the attractions of hospital life. The Labour Party has just issued a draft report which will be submitted for consideration to a conference of nursing and kindred organisations to be held in the Caxton Hall, Westminster, on Jan. 28th, 1927. An account of average conditions throughout the country has been compiled, from answers to a questionnaire as to social and educational qualifications, period of training, deposits, wages, hours on and off duty, holidays, meals, living accommodation, superannuation, and so forth. Various recommendations are made, from which we select some of those relevant to the training schools. The Labour Party agrees with Miss NUTTING in advocating the need of financial provision for the training schools, and of separate administrative authority. In order that the probationer's time should be entirely given over to the study and practice of her profession, they also suggest an increase in the permanent nursing staff and the delegation of cleaning duties to maids and orderlies as soon as the probationer has received adequate training in their performance. Among the more important specific recommendations are the equivalent of the school-leaving certificate as the educational standard for admission, four months' preliminary instruction in elementary physics, chemistry, anatomy, and physiology, and a period of training covering two years and eight months. (It will be remembered that the report on Nursing Education, quoted above, has suggested a reduction to a concentrated course lasting two years and four months.) It is recommended that there should be no contract of service beyond a month's notice on either side, and that a 48-hour week with an eight-hour day, inclusive of lecture hours, should be the standard. Consecutive night duty should be limited to three months, and no untrained nurse should have full responsibility for a ward by night or by day. Not less than one free day a week, a week-end per month, and three weeks a year should be allowed. The uniform should be reconsidered and designs adopted "more in accordance with the comfortable dress now worn by women in other employments."

Many of these recommendations are neither new nor revolutionary, and, indeed, reflect the practice current at some hospitals. An exception is the high standard required for preliminary education, which could hardly be enforced until recruits are more numerous; the same may be said for the reduction in the period of training. The least logical recommendation is No. III. 9 which reads "Salaries during training should be sufficient to meet all needs, including holidays, and at present £40 per annum should be the minimum." It is unreasonable to expect hospitals to provide larger salaries for probationers if the amount of routine work they are to do is simultaneously to be reduced. While there should always be a channel through which suitable candidates without private means may take up nursing, there is general agreement among those who have the highest ideals for the profession that it is undesirable to bribe probationers to enter the service of hospitals by the promise of a high initial wage, which is only economically possible if earned by unskilled work. The draft report gives no specific suggestion as to the salary that a fully trained nurse doing private work or attached to a voluntary hospital should command, recommending the organisation of the profession on trades-union lines and the subsequent formation of a National Joint Council to work out scales. We doubt whether this recommendation will be favourably received in the nursing profession, where the relation between individual employers and employed is peculiarly intimate. On the whole, however, the document is a moderate and fairly accurate presentation of the position of the nursing world to-day. If it over-estimates the effective demand for the highly skilled educated nurse, and under-estimates the public need for a supply of deft reliable workers to attend to the household as well as to its sick members, this lack of perception is not peculiar to the Labour Party.

FILTER PASSERS AND INCLUSION BODIES.

THE zealous search for microscopic forms of parasites in the tissues of animals infected with diseases of unknown cause has resulted in many finds of very varying interest and importance. The ultra- or infra-microscopic viruses have been commonly designated filter-passers since the first discovery of the filterability of the virus of mosaic disease in plants by Iwanowski in 1892 and Beijerinck in 1898, and of foot-and-mouth disease by Löffler and Frosch, also in the latter year. Since then 40 or 50 such viruses causing infective diseases in animals have been

placed by different observers in this group. The chief reason why pathologists have assigned so many to a single category seems to be the inability to recognise an infective agent microscopically. The criterion of filterability is less definite than that of visibility and the former character varies very much in the case of different diseases. The ability of the virus of many diseases which have been placed in the group to pass a fine porcelain filter is doubtful. The discovery of these abnormal bodies inside the cells of the host has been recorded chiefly in these diseases, perhaps partly because in them the search for visible causative agents has been keener. In some cases the inclusion bodies are not very readily demonstrated nor very uniform in appearance, but in others, such as vaccinia and rabies, they are of very real characteristic and even diagnostic importance. The attempt to explain the association of such large forms with an infra-visible virus has led to the invention of the name chlamydozoon for the hypothetical micro-organism on the view that it was covered by them as with a garment. R. J. Ludford and G. M. Findlay, in the *Journal of Experimental Pathology* for October last, declare that this name now implies a widely discredited hypothesis and is merely a cloak for ignorance. Nevertheless, the bodies themselves and their riddle have an abiding influence, and these two workers have given a valuable aid to their study by the pictorial review of 22 such microscopic appearances culled from the literature of diseases due to ultramicroscopic viruses. Representations of bodies whose nature is unknown are necessarily vague or diagrammatic and the authors have not even drawn them all on the same scale. But they have well indicated the variety in form and position in the cell of these objects and the extent of the problem which remains unsolved. It is well to be reminded from time to time of the large range of infective diseases the nature of whose cause is quite unknown, and this survey of the observations already made should assist their comparative study. The same writers give a detailed account in the same number of their observations on the cytology of fowl-pox. They endorse the view most widely held at present that the inclusion bodies here are not parasites but pathological structures belonging to the host.

DR. ESSEX WYNTER'S GIFT.

A GREAT and discriminating piece of generosity was recorded last week, when, at a meeting of the governors of Middlesex Hospital, it was announced that Dr. Essex Wynter had given to the hospital his beautiful private house, Bartholomew Manor, Newbury, together with a large group of sixteenth century cottages and the surrounding land. Major Astor, in making to the court of governors an official declaration of the gift, added that Dr. Essex Wynter not only proposed to dedicate, after the death of himself and his wife, his fourteenth century home and its dependencies of nearly an equal antiquity to be held in perpetuity as a home for retired members of the nursing staff of the Middlesex, but with extraordinary open-handedness was providing an endowment fund for the maintenance and upkeep of the property. A side of Dr. Wynter's gift which marks its deeply personal character is that he is presenting to the institution, with which he has been so long and honourably associated, a property over which he and his wife have watched with loving care. Through their personal skill and work the old manor house and the cottages on the estate have been intelligently repaired, while the surrounding land has been repurchased, securing a suitable and unspoilt environment for the buildings. Already two of the cottages have been reconstructed to form self-contained homes, which are now occupied by nurses, giving a practical example of what this fine gift to the hospital will eventually imply. The son of a great London medical school has in this beautiful gift recognised in a practical yet moving way indebtedness to his home of learning and the theatre of his life-work.

Annotations.

"Ne quid nimis."

BIOLOGY AND HUMAN LIFE.

THE problems of mental deficiency in their relation to the health of the community in the present and the future is beginning to attract the attention which it deserves. There are, says Sir George Newman in a recent report,[1] 33,000 children in England and Wales returned as mentally defective, and some 200,000 more as exceptionally dull and backward. Neglect of these children at the stage when something can be done for them leads to a great mass of unemployability, industrial incapacity, delinquency, and even of crime when they grow up. The conference, whose concluding session is reported on p. 1283, considered these problems of mental deficiency from many different aspects. Sir Leslie Scott laid down what he thought was a reasonable aim—namely, effective control of such defectives as are anti-social or unbalanced, leaving for communal care those who in the right environment can live a fairly happy and useful life. As to the form which this control should take opinions were sharply divided. It is only the Eugenics Education Society which has as yet had the courage to draw up an outline of a practical eugenic policy.[2] But it is not only eugenists who feel that man has gone so far in bringing his physical environment into subjection that it is about time he set about making himself more worthy of his surroundings. Such is, for instance, the theme of Prof. Julian Huxley's Norman Lockyer Lecture delivered last month before the British Science Guild. Modern biology has, in truth, come nearer our daily lives than some people remember, and possibilities of deliberate human improvement have come very near, if they have not already entered, the field of practical action.

Broadly speaking, there are two schools of thought on the subject. One is fired by the new knowledge of heredity, vitamins, and the like, and observes how successfully biology has dealt with the parasites of men, animals, and plants. It asks that our knowledge should be vigorously applied and that active reform should be instituted. Prof. Huxley in particular urges the pressing urgency of doing something about birth control and the necessity, rather less immediate perhaps, of a eugenic programme. He views human increase as inevitably leading to disaster, and would have us weed our population and breed our population as we weed our gardens and breed our cattle. The other school is biological, too, though it consists more of naturalists than of experimentalists. It reflects on the fact of experience that animate nature is a wonderfully good fit and that the components live in a harmonious adjustment with one another, which seems to be instinctive or automatic; that the disturbance of this whole which follows the disturbance of one of the parts is apt to extend to a breadth and length which we cannot predict; and that after such a disturbance the components will settle down into a new whole, which will be as stable as its forerunner until its constituents or surroundings are altered. It believes, in fact, that live things regulate themselves quite well and that man has not lost his animal characteristics so completely that he has none of this capacity for automatic regulation left. In its most complete form it is the school of *laissez faire*.

Most ordinary people will want some compromise. Biological knowledge is great, but biological ignorance is greater, and hardly anyone will be prepared to give themselves over to a life ordained and directed by

biologists. It is sufficient to recall what would have happened if we had all kept strictly to the diet which the physiologists of 1910 would have told us was complete and adequate. They will agree that it is very proper to weed your garden, but that it is rather dangerous to do it too thoroughly before you have made up your mind quite clearly which plants you are going to class as "weeds." They will agree that selective breeding might do as much for men as for cattle if we can settle what we are going to breed for before we begin. And if they are of the sort which wants to do something, they will probably come to the conclusion that it would be good to pull up the very worst and undoubted weeds and to leave the speedwell in the cabbage patch for the sake of its beauty and cheerfulness, though it is not much use to eat, and to encourage the making of good and clever people without putting too many obstacles in the way of those who are not so obviously desirable but out of whom astonishingly fine children sometimes come. And of birth control they seem to know as much as is necessary already. Anyone with eyes to see can perceive the progress which our community as a whole has made—physically, mentally, morally, and spiritually; it is a sight which more than anything else encourages those who look for further advance. Prof. Huxley tells us that we "are becoming a scrub herd of mongrels." If it were in any degree true it would be depressing; fortunately it is not.

THE TOXÆMIA OF INTESTINAL OBSTRUCTION OR PARALYSIS.

A CLINICAL and experimental investigation [1] into the causation and treatment of the toxæmia associated with intestinal obstruction and peritonitis has been made by Mr. B. W. Williams at St. Thomas's Hospital. It is a matter of common observation that constipation or intestinal obstruction in the large bowel gives rise to no acute toxæmia until the stagnation extends to the small intestine, and on Mr. Williams's theory this fact is easy to understand. The arguments on which his hypothesis is based are clearly set out. The author first draws attention to the similarity of symptoms in acute obstruction and in the late stages of acute peritonitis and to the resemblance both bear to the clinical aspect of anaerobic toxæmia resulting from war wounds. He suggests the possibility that in all three conditions the patient is suffering mainly from an acute toxæmia resulting from abnormal proliferation in the obstructed intestine of anaerobic organisms. The normal distribution of anaerobes in the intestinal tract is then discussed. *B. welchii* requires for its growth and the production of toxin an anaerobic medium which should be neutral or slightly alkaline. In acid medium the toxin is destroyed and the bacillus would be rapidly outgrown by other organisms. The lower part of the ileum is the only section of the intestine where the optimum conditions are fulfilled, but normally the passage of material through the small intestine is extremely rapid and the period during which the reaction is suitable for proliferation would be very brief. On the hypothesis set out by Mr. Williams there should be a great proliferation of *B. welchii* in the small intestines of patients with acute obstructions, and an examination of suitable post-mortem material an enormously increased quantity of this bacillus—among many others—was indeed obvious. Animal inoculations showed, moreover, that not only the bacillus itself, but the presence of its exotoxin, could be demonstrated in the contents of the small intestine in advanced obstruction in human cases and in cases where the obstruction had been experimentally produced in animals. The next step was to attempt to find evidence that *B. welchii* toxin is actually absorbed from the intestine in these cases and is responsible for the toxæmia. Mr. Williams claims that the clinical features of late cases and the presence of fine fatty degeneration in the heart and liver of patients dying of acute obstruction and of peritonitis are compatible with the absorption of *B. welchii* toxin and that the intravascular hæmolysis shown in the endothelium of the heart and great vessels, in the absence of evidence of infection with other hæmolytic organisms, is strong corroboration of such absorption. The final test of the hypothesis, however, was the administration of *B. welchii* antitoxin in suitable cases of peritonitis and obstruction. It was decided to use cases of appendicitis for the clinical trial because (1) a fairly large number of cases are available at St. Thomas's Hospital, (2) cases which are "going wrong" give fair clinical warning, (3) the mortality is well established and fairly constant between 5 and 10 per cent. It was decided to administer serum to all cases in which clinically the chances of survival appeared to be 50 per cent. or worse. This included (*a*) moribund cases of severe general peritonitis; (*b*) streptococcal peritonitis, unlocalised, in children under 12 years; (*c*) cases which after appendicectomy continued to show signs of advance of the disease by rising pulse-rate, abdominal distension, and toxæmia. In order to increase the number of available cases the coöperation of three other surgeons was enlisted.

The series consisted of 256 consecutive unselected cases of which 18 of the most severe were treated with *B. welchii* antitoxin. In the series there were three deaths, giving a mortality of 1·17 per cent. During 1925 a control series of 111 cases, also consecutive and unselected, under surgeons who were not using the antitoxin, gave a mortality of 6·3 per cent. The clinical effects of the administration of antitoxin were often striking and immediate, restlessness being diminished or abolished, cyanosis disappearing, and sleep ensuing. The pulse-rate fell in cases of very marked toxæmia though not for a day or two, abdominal distension disappeared, though sometimes slowly, and the bowels began to act spontaneously. Similar clinical effects were observed after the use of antitoxin in a much shorter series of cases of obstruction, and though the author is careful to point out that similar signs of improvement may and commonly do follow the simple surgical relief of obstruction, and that the series is too short to be at all conclusive, the fact remains that of 54 cases of acute intestinal obstruction only five died, the normal mortality being 24·8 per cent. Mr. Williams gives suggestions for dosage and indications for treatment with *B. welchii* antitoxin for the benefit of those who wish to try a method which is still in the experimental stage and discusses its disadvantages. These include the sensitisation of the patient, the possible production of rashes, the remote risk of anaphylaxis, and lastly the expense involved. The serum is costly and if it is to be of use large amounts must be given. The vast majority of cases of acute appendicitis, however, will recover by treatment on ordinary surgical lines. In cases which develop signs of intestinal obstruction or paralysis and toxæmia, however, the mortality is very high and the disadvantages of serum therapy are of less moment. It is therefore to be hoped that a trial will be given to this method of treatment which is, of course, only ancillary to the relief of obstruction or the removal of the cause of the peritonitis.

THE HOSPITAL SAVING ASSOCIATION.

THERE is no check to the progress of the Hospital Saving Association. The report for the year ending last July, which has just been made available, shows that an organisation established so recently as 1922 has already an income of £150,000 and 267,000 contributory members, more than 100,000 of whom joined during the last 12 months. Since the rate of increase works out at over 2000 members a week the total must by now be considerably larger, while the income is growing in proportion. No doubt it would be unduly optimistic to suppose that the present rate of progress will continue indefinitely—three years

ago there were 15,000 members and the revenue was £22,000—but the number of persons eligible for membership is so large that there is abundant room for further expansion; there are hundreds of thousands of eligible persons in the London district who have yet to realise the advantages of a system of health insurance of which the premium is only 5*d*. a week. At the sacrifice of ten cigarettes a fortnight the insurer is made free of hospital treatment not only for himself or herself but for all dependents living under the same roof. The income limit, moreover, is wide, and entry is permitted to the single person earning up to £4 a week, to the married person without children under 16 up to £5, and to the married person with such children up to £6. When such advantages are to be enjoyed at so trifling a cost it is not surprising that the great army of people who earn small incomes should be eager to qualify for them. Nor are the insurers the only beneficiaries, since last year the hospitals received over £80,000 in return for their work for the Association. Many of the hospital authorities regard the Association's work as a prop to the voluntary hospital system—a prop that will do much to prevent it from falling into the hands of the State or municipalities—whilst it is claimed that experience shows that the general practitioner is in no way injuriously affected. A year ago Lord Hambleden, the chairman, prophesied that the membership would, in time, reach a million, and the progress that is being made suggests that the Association will hardly have reached its 'teens by the time the prophecy comes true.

PLASMOCHIN.

WE have already given some account of the properties of plasmochin, a synthetic remedy for malaria, whose discovery was announced at the conference of Naturforscher and Ärzte, held at Düsseldorf in September.[1] A recent supplement to the *Archiv für Schiffs- und Tropen-Hygiene* (vol. xxx., 3) reports in full the four papers communicated to the conference. The first is by Dr. H. Hörlein, director of the drug department of the Elberfeld factory, where plasmochin was developed, who points out that quinine is so unpleasant to take, has such troublesome after-effects, and is so expensive, that the ever-optimistic chemist felt he ought to make something to replace it—preferably something which would destroy the malarial crescents which infect mosquitoes. It was a study of quinine synthesis that led Perkins to his first coal-tar dye, mauvein, in 1856, when quinine was thought to have two chinolin rings in its molecule; this idea, says Dr. Hörlein, was in 1890 proved mistaken by the work of the Elberfeld dye factory. Quinine he describes as an alkylamino-6-methoxychinolin, and he adds that plasmochin is something similar. More than that he will not say, because so many countries allow pirating of chemical work, though these researches are in the highest interests of mankind. Plasmochin, like Germanin (Bayer 205), is the outcome of the joint work of the chemical and chemotherapeutic sections of the Elberfeld factory, and in the second paper Dr. W. Röhl, head of the chemotherapeutic laboratory, takes up the tale of its investigation. Human malaria, he says, attacks only men and apes, but bird-malaria, an infection with *Plasmodium relictum* (formerly Proteosoma) carried by *Culex pipiens*, is influenced by quinine, and is easier to work with. He devised a method of dosing canaries by means of an œsophageal catheter, a known quantity of the drug being passed into the stomach. When a bird is infected by intramuscular injection, parasites appear in the blood in five days; if quinine hydrochloride is given for the first six days after injection they do not appear till after the tenth. The dose of quinine for a bird of 20 g. is 1 c.cm. of a 1/200 or 1/800 solution; higher dilutions are ineffective, and lower dilutions are harmful, and so Dr. Röhl puts what he calls the "working margin" of quinine at 1 : 4. Using this technique he investigated hundreds of drugs for a long time without result. Finally he tried plasmochin, and found that 1 c.cm. of a 1/50,000 solution, given daily for six days, delays the development of the plasmodium as well as quinine in dilution of 1/800; the drug is, therefore, 30 times as powerful. Birds take it well up to 1 c.cm. of 1/1500 solution, so its "working margin" is 1 : 30; it is thus much more convenient than quinine. When an already infected bird is treated there is no effect on the first day, but by the second all the larger parasites, including the gametes, have disappeared or degenerated. The vast majority are killed, the destruction being due to direct action on the parasites, and not, Dr. Röhl considers, to increase in antibody formation, for plasmochin has no effect on an infection made two hours after its administration. It is the first synthetic drug found useful against avian and human malaria. Prof. F. Sioli, of Düsseldorf, describes how plasmochin was tested in the treatment of general paralytics inoculated with tertian malaria. The daily dose at first was 0.75g., and was gradually raised. The fever ceased at once, but relapses occurred. The most satisfactory course was found to be 0.75 g. a day in 2 or 4 doses, continued for three days after fever had gone and parasites had disappeared, the same dose being then given every fourth day for two or three weeks. There were no deaths, and the only complication was a cyanosis which stopped treatment, it being always found that the patient was then cured. Plasmochin, says Dr. Röhl, cures the tertian malaria of general paralytics, and can be confidently recommended. The last paper is by Prof. P. Mühlens, of Hamburg, who gives an account of his experiences in treating natural malaria in Hamburg. During his investigations he laid special stress on making exact blood examinations daily, and had the doses administered by his own assistants, so as to be quite sure what doses patients were actually taking. The plasmochin was generally given in 0·3 g. tablets, and when the patients got about 2 g. in a day they complained of pain in the stomach, which disappeared when the dose was reduced. Large doses produced a slight cyanosis of tongue, gums, and nails, which was not, he thought, toxic, but vasomotor. A daily dose of 1·5 g. caused the parasites to disappear in five to seven days, and then after an interval of four to five days further doses were given for three days. The whole course lasted four to six weeks, but was difficult to enforce, as the patients (there were 134 of them) felt so well that they were apt to leave the hospital too soon. Relapses were rarer in tertian and quartan malaria than with quinine, but, if plasmochin was used alone they were more frequent in tropical malaria, because, though plasmochin deals effectively with crescents, it has less influence on the small ring forms than quinine. After plasmochin even late relapses showed no crescents, whereas they were still present after quinine. This disappearance is held to prove that they are formed in the peripheral circulation. As quinine and plasmochin seemed to be auxiliaries, they were given together, in tablets containing 0·15 g. plasmochin and 2 g. quinine, three of these being taken every day. Under this treatment relapses ceased to occur. The tablets fall to pieces in water, becoming a suspension which children take readily. As for acute malarial fevers, says Prof. Mühlens, 250 cases have been treated in the Balkans, and many in Spain and Italy; the new drug has been as successful in curing them as it has proved itself in Hamburg, whilst blackwater fever has also been satisfactorily treated. He summarises the position by the statement that plasmochin seems to cure malaria more easily than any other drug, and, above all, it kills the gametes and so lessens the chance of infecting mosquitoes and further spreading the disease. It has also been used for prophylaxis in a dose of 1·5 g. twice a week for nine weeks in West Africa, apparently with great success.

Prof. Mühlens ends his paper with well-deserved compliments to the Elberfeld factory and its staff.

MEDICAL FEES AT INQUESTS.

AFTER a long voyage the Coroners (Amendment) Bill, embodying reforms recommended many years ago by Sir Mackenzie Chalmers's Committee, has at last reached harbour. Twice its progress was interrupted at the Committee stage in the House of Commons for the tiresome and not very creditable reason that a quorum of 20 Members of Parliament could not be found. Each of these set-backs consigned the Bill to the bottom of the Parliamentary list, but, fortunately, the items above it were disposed of with unexpected rapidity, and, when at last the Committee stage was reached, various proposers of alterations generously forebore to press their amendments. In its present form—as may be seen from our Lobby Correspondent's report—the Bill has not been greatly changed from its original wording. The disqualification clause at the beginning now covers the holding of the office of mayor as well as that of councillor or alderman of the local authority which appoints the coroner. A new clause empowers the Coroner of the King's Household—an officer whose labours are, happily, not heavy—to appoint a deputy. The main change in the final stages of the Bill was the insertion of a clause fixing the fees of medical witnesses. At first the Home Office were to give 1 guinea to a practitioner attending an inquest whereat he has made no post-mortem examination, 1½ guineas for making a post-mortem examination and reporting the result to the coroner without attending to give evidence at the inquest, and 2 guineas for a post-mortem examination, report of result, and attendance to give evidence. In the final Committee stage amendments moved by Sir Richard Luce and Dr. F. E. Fremantle succeeded in slightly raising all these fees. The fee for mere attendance is increased to 1½ guineas for each day on which the practitioner is required to be present; the post-mortem fee is raised from 1½ to 2 guineas; and the inclusive fee of 2 guineas for post-mortem examination, report, and attendance is brought up to 3 guineas for the first day and 1½ guineas for every subsequent day on which attendance is required. Even with these increases the fees will hardly compensate practitioners for the loss of practice which a visit of uncertain duration to a coroner's court involves; but the advance goes a little way towards approximation with modern standards of money value. The Act takes effect next May; meanwhile the Expiring Laws Act will continue the temporary provisions (as to number of jurors and as to inquests without juries), which will then be superseded.

DIFFUSE GASTRIC POLYPOSIS.

Dr. Harold Brunn and Dr. Felix Pearl,[1] of the Surgical Services of the University of California Medical School and Mount Zion Hospital, remark that diffuse gastric polyposis, otherwise known as polyadenoma, adenomatosis gastrica, or papillomatosis gastrica, is apparently a rare disease, as they have been able to collect only 84 cases from the literature from 1820 to 1925, including five proved cases and seven probable cases which came under their personal observation. The average age of the patients was 54 years, the youngest being 20 and the oldest 82. The proportion of males to females was 3 to 2. Gastric polyposis may be either congenital in origin or arise from an inflammatory basis. It is noteworthy that Fibiger and Wassink were able to produce polyposis experimentally in the stomachs of healthy rats by feeding them with nematodes or cockroaches containing nematodes. Gastric polyposis may appear either as district polypi adenomatous in nature or as slightly elevated hypertrophic plaques which are probably telangiectatic in origin. The symptoms and physical signs are not characteristic, and frequently the condition is not detected until autopsy, as occurred in all the cases on record up to 1909. When present the symptoms are of the same type as those found in any gastric disorder, consisting in epigastric discomfort, distension, and vomiting. The writers regard achylia as the most significant finding, and are of opinion that in combination with fresh blood and abundant mucus it should suggest the diagnosis of gastric polyposis. The most valuable diagnostic aid known is found in a properly interpreted skiagram which shows irregular defects in the margin of the gastric shadow at the site of the tumour. Some help may also be obtained from gastroscopy and examination of shreds from gastric washings. The treatment is entirely surgical. Owing to the tendency of these tumours to become malignant, as much of the tumour-bearing area as possible should be excised. Local infiltration with or without splanchnic block is the proper method of anæsthesia to employ.

ST. PETER'S HOSPITAL.

IT is not very easy to collect money for small hospitals which deal with special complaints, and the difficulty is increased when the building is hidden away in some inconspicuous street. St. Peter's Hospital, though barely a hundred yards from the Strand, is so remote from the line of traffic that relatively few Londoners have even heard its name, and it is handicapped in any appeal to the general public by the special nature of its work. By its services to surgery, however, this hospital has deserved and won a reputation amongst medical men in all parts of the world. As a centre for teaching and for developing the technique of operations on the urogenital tract its name stands high—so high that when Sir John Thomson-Walker visited Canada recently he found that 60 per cent. of the many hundred practitioners whom he met had visited or taken courses at St. Peter's. The work on prostatectomy done by Sir Peter Freyer did much to bring the institution into prominence, and that this prominence is maintained is clear from the fact that every year 900 medical visitors come to examine its methods—to see the practice of a hospital with only 32 beds. For something like 40 years even these few beds have been supported with increasing strain, and nowadays at least three operable patients present themselves for every bed that is available. Although enlargement of a hospital does not necessarily mean improvement of its service, it is obvious that St. Peter's has a right to the support that will make extension possible. Nearly half the annual income is provided by the patients themselves, and the present appeal is especially for £50,000 required to enlarge the hospital by absorbing a line of shops, from which at present a considerable income is derived. Without any special public announcement some £5000 has already been raised by friends and sympathisers, and an attempt is now being made to interest a larger number of people. Some of our readers may, perhaps, have patients to whom the work of St. Peter's would particularly appeal.

TROPICAL MEDICINE AND THE LONDON SCHOOL.

THE study of tropical medicine becomes more important every year. As the commercial exploitation of tropical products widens, more and more Europeans find employment and settle, with their wives and children, in countries of exacting climates and strange indigenous diseases. Moreover, the demand for these products draws more and more natives from their villages and herds them into large settlements, where, unless skilled health administrators are at hand to discover and enforce the laws of hygiene, they become a prey to epidemics far more virulent than those of temperate countries. Much of the knowledge that makes life possible under these conditions has been gained by the London School of Hygiene and Tropical Medicine and its forerunners, and perhaps no body of research workers has contributed so much that is of immediate

vital importance. The work of this school is periodically reviewed in "Collected Addresses and Laboratory Studies," [1] the second volume of which, compiled by Prof. R. T. Leiper, has lately appeared. The rather dull title belies the contents. The laboratory studies are, of course, highly technical records, but the ordinary reader will find the book worth getting if only for the three addresses by Dr. Andrew Balfour, Director of the School. In the first of these, entitled Why Hygiene Pays, he reviews what has been achieved, and its value in the promotion of health in tropical dependencies. The second is called Some British and American Pioneers in Tropical Medicine and Hygiene, whilst the last and shortest, Some Landmarks in Tropical Medicine, points out the way by which the epidemic diseases of plague, yellow fever, filariasis, and cholera were fought and conquered. Of the laboratory studies not a few will interest others besides specialists in the particular subjects, which range from human entamœbiasis in temperate zones and the differentiation of food poisoning bacteria to Dr. P. A. Buxton's interesting inquiry—not strictly a laboratory study—into the causes of the depopulation of the Melanesian Islands. The volume also contains a description of the recent laying of the foundation-stone of the school's new home in Keppel-street. The annual report of the school, presented to the governors on Dec. 7th, states that progress with the building has been seriously delayed by the dispute in the coal industry, but it is hoped to put up all the steelwork within five or six months. In the meantime the number of students is increasing and the work of the Institute of Agricultural Parasitology continues to expand under Prof. Leiper's direction. The Ministry of Agriculture has converted its grant to the Institute into a block grant of £5000 a year. The question of the hospital at Endsleigh-gardens is still in abeyance, the Seamen's Hospital Society having announced its intention to maintain it for a limited period only, and the Minister of Health has appointed a committee, of which Sir Alfred Mond is chairman, to report on how the necessary clinical and pathological facilities can afterwards be secured to the School. The arrangements for financing the work of the School are incomplete and representations were made to H.M. Treasury as long ago as 1925 that the commitment of £25,000 a year entered into by the Government when the Rockefeller gift was accepted, would fall far short of the requirements for the staffing and upkeep when the School is fully established in the new building. The suggestion has been made that additional funds might be raised, in support of the Tropical Division of the School, from Colonial Government and commercial sources, so as to ease the burden on the Imperial Exchequer. The board is at present exploring this possibility.

THE POST-ENCEPHALITIS UNIT.

AT their meeting last Saturday the Metropolitan Asylums Board received a report on the first complete year's working of the post-encephalitis unit opened in the autumn of last year at the Northern Hospital, Winchmore Hill. This unit, consisting of four pavilions, each of 25 beds, was fully occupied almost from initiation. Its arrangement and intention were dealt with in a valuable report by the consulting neurologist, Dr. S. A. Kinnier Wilson, which appeared not long ago in the Board's annual report for 1925–26.[2] Dr. Wilson then enunciated the principles on which patients were admitted and the type of case in which improvement was likely to follow the measures employed, but he then warned the Board how diverse are the sequelæ of the disease, as diverse indeed as its phenomena, and he regarded the clinical material of the unit as likely always to be heterogeneous. Special investigation would be needed to decide to what extent behaviouristic defects and apparent changes in personality were in actual fact the outcome of the brain disease. Dr. G. A. Borthwick, medical superintendent of the Northern Hospital, in his report[3] on the first year's working, amplifies what Dr. Wilson has already set out, and states that the unit has not been productive so far of any very positive curative results. Its future value may be rather that of a clearing-house for cases suffering from any of the many residua of the disease, where they may be observed, classified, and allocated in various ways. For children showing psychic changes a period of residence at a hospital school should prove the best line of treatment, with release to their homes when their condition improved enough to justify it. The hospital school should also suit the children with Parkinsonian syndrome who, as a rule, presented little mental disturbance and were well behaved; the milder cases of this type could attend an ordinary special school for physical defectives. Patients showing excito-motor phenomena had not improved appreciably, despite treatment, and Dr. Borthwick thinks the slighter cases with little or no psychic change might be allowed to return home, leaving the bedrid cases in hospital or infirmary. The same policy would apply to cases with definite paralysis, for it is the experience of the unit that this shows no tendency to improve; nor have the cases of endocrine disturbance responded to treatment. Maniacal outbursts require transference to a mental hospital, where constant supervision is available; the mentally deficient class comes under the Mental Deficiency Act of 1913 in certified institutions. In hopelessly bedrid cases an apparently lifeless appearance may conceal remarkably good intelligence, and some provision for occupying their minds should be made. Dr. Borthwick recommends the continuance of the unit for at least another year, and in this the Infectious Hospitals Committee concurs. In an appendix to the report Dr. T. H. Whittington, visiting oculist, remarks on the number of children who showed a tendency to ocular divergence, a percentage of 37 taken all round. Many of the children had poor sight owing to errors of refraction, and five at least were found to have vision such as would make them quite unable to see any writing on the blackboard. Routine ocular examination is essential to make the best use of what powers of mental appreciation these children retain. At the end of the year under review there were 93 cases in the unit, 133 cases having been admitted and 40 discharged. Of these 12 were improved, 6 in such a condition that they were unlikely to improve by further treatment, 4 proved unsuitable for the unit, and 18 were taken away at the request of the parents. There was no death in the unit.

Lord D'Abernon has accepted the chairmanship of the Industrial Fatigue Research Board, to which he has been appointed by the Medical Research Council. Mr. William Graham, M.P., has relinquished the chairmanship of the Board under the pressure of other public work, but will remain a member of the Board.

CHELSEA CLINICAL SOCIETY.—The next meeting of this society will be held at the Florence Restaurant, Rupert-street, London, W., on Tuesday, Dec. 21st, at 8.30 P.M., when there will be a discussion on Septicæmia, in which Dr. A. P. Beddard, Dr. J. Freeman and Mr. J. E. McDonagh will take part. The meeting will be preceded by dinner at 7.30 P.M.

SOCIETY FOR THE STUDY OF INEBRIETY.—On Tuesday, Jan. 11th, 1927, at 4 P.M., at the rooms of the Medical Society of London, Chandos-street, Cavendish-square, W., Commissioner Adelaide Cox, of the Women's Social Service Department of the Salvation Army, will open a discussion on the Inebriate Woman. Members and associates are at liberty to introduce visitors.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCII.

TREATMENT OF RAYNAUD'S DISEASE.

IF the arterial supply to a part is cut down the part becomes cold, but its colour depends upon whether the capillaries and venules are empty or engorged; in the former case the part is white (*local syncope*), in the latter case blue (*local asphyxia* or *cyanosis*). In the worst cases gangrene will result. Such, in brief, is the order of events when a normal part of the body, such as the hand, is exposed long enough to cold to produce frost bite; and the same series of changes occurs in the subject of Raynaud's disease as the result of but little exposure. The asphyxial and gangrenous fingers are very painful. Gangrene may supervene directly on the local syncope stage. Raynaud himself suggested that disturbed innervation of the capillary vessels was responsible, and recent work has fully brought out the fact that the capillaries are as important as the arterioles in altering the supply of blood to a part. A frequent subject of Raynaud's disease is a young woman who suffered from chilblains as a child, and as an adult is permanently afflicted with so-called "beef steak" hands. In long-standing cases of the disease the skin over the extremities becomes sclerodermatous, while the joints present features similar to those of rheumatoid arthritis. At the end of an attack the affected parts become abnormally hot and the patient complains of a feeling of pins and needles. In fact, a temporary erythromelalgia results. The clinical features characteristic of Raynaud's disease may be due to any cause which interferes with the arterial blood-supply, such as syphilitic arteritis or thrombo-angiitis obliterans. The trophic changes, often resulting in gangrene, that occur in syringomyelia must be distinguished. Local gangrene, which can hardly be confused with Raynaud's disease, is well known in malaria and in certain other fevers. Pathomimia, or multiple skin gangrene, and ergotism would be extremely rare sources of error in the diagnosis.

In Raynaud's disease proper there is no obvious cause for the obstruction; it has been attributed to vasomotor spasm. Occasionally the presence of a cervical rib or sarcoma of the spinal cord have produced a condition which is indistinguishable from Raynaud's disease, by causing irritation of those sympathetic fibres which function as the vasomotor nerves of the hands. Raynaud's disease has been observed to result from poisoning by arsenobenzol. That this disease is not merely a local affection of the hands and feet is shown by the facts that the ears and the tip of the nose occasionally become gangrenous and that associated changes may occur in other organs. The central nervous system may be affected in various ways. Temporary monoplegia, hemiplegia, paraplegia, and aphasia have been observed. Amblyopia has been shown to be due to a narrowing of the retinal arteries, while the veins are dilated and pulsating. Colic may be explained by similar changes in the wall of the alimentary canal.

General Measures.

Raynaud's disease is thus a general condition, and its manifestations are due to vasomotor disturbances in various parts of the body; sources of worry must be removed as far as possible; patients are often inclined to neurasthenia or hysteria; the general health of the patient must be improved if possible, and sources of local sepsis removed; he may be well advised to spend the winter in a warm country, such as Egypt. Syphilis, quite apart from its liability to produce arteritis, is recognised as a possible primary factor, and antisyphilitic measures should be adopted if there is any indication that syphilis is present in an active stage. Where the uric acid in the blood is high, treatment with one of the cinchophen compounds such as atophan, agotan, phenoquin, quinophan, should be considered, the usual dose being 15 gr. t.d.s. three days in each week, or atoquinol in doses of 4–8 gr., also t.d.s.

Einhorn's Duodenal Saline Treatment.—In his book on the duodenal tube, Einhorn states that the administration of large quantities of normal saline through a duodenal tube abolishes the clinical features of Raynaud's disease. I have confirmed this statement in several cases. The saline (0·85 per cent.) must be administered in sufficient quantity to produce fluid motions, should be boiled by way of sterilisation before use, and should be at body temperature when administered. The treatment is best carried out in the morning. A light breakfast may be allowed on waking. An ordinary stomach-tube or thin tube such as is employed for fractional test-meals or a long nasal tube may be used. It is unnecessary to make certain whether the tube has really passed into the duodenum; it is only necessary to see that the 28 inch-mark is at the level of the teeth and to get the patient to lie on his right side. Two pints of the saline are run in to begin with, and subsequently 1 pint every half hour until about 8 to 10 pints have been administered. The only precaution necessary is to make certain that the lungs remain clear, because it is possible to produce œdema of the lungs by this means. If the patient feels any discomfort from fullness during the administration less fluid must be given. This treatment may be carried out for four or five days in the week for a period of two or three weeks. In quite mild cases 2 pints of saline may be drunk in the morning.

It is of great interest to consider why this treatment is effective; the clue to this problem lies, I think, in an observation made by Sir Arbuthnot Lane, who removed the large intestine of a man with very bad Raynaud's disease. The case has been fully described by Mutch (*Brit. Jour. Surg.*, 1915, ii.. 608). For a number of weeks the symptoms completely disappeared, but they have since gradually returned. This suggests that there was something in the intestine that caused the condition, and this is borne out by the success obtained by Einhorn's treatment. The treatment is not a cure because the symptoms are apt to return, especially during the next spell of cold weather; but the patients I have treated have stated that their subsequent attacks have not been so bad.

Intravenous Injection of Radium Emanation in Normal Saline.—Another treatment just devised by Dr. Tominek, of Prague, of which I have no experience, attacks the disease at presumably the next stage—viz., by preventing the local action of the peripheral vasomotor nerves. He uses intravenous injections of radium emanation in normal saline. The dose is 2–3 millicuries, gradually increased to 15 millicuries. He suggests that the radium is antagonistic to adrenalin, which is responsible for the spasm.

Surgical Measures.

Surgical treatment of the disease would, naturally, only be considered in the most intractable cases. Two methods of procedure have been carried out.

(1) Leriche, in 1913, described the results he had obtained by removing the periarterial sympathetic fibres round the femoral artery, so that vasodilatation resulted, and the limb became warmer. Injection of alcohol round the artery is another method that has been used with the same object.

(2) Quite recently Davis and Kanavel, believing that the vasomotor fibres to the limb ran chiefly through the white rami into the spinal nerves, have removed the lower and middle sympathetic ganglia of the sympathetic chain of the neck. The lumbar sympathetic ganglia were removed by the lumbar or intra-abdominal routes when the legs were affected. They exclude, as far as they can, those cases where the vessel wall is diseased.

The first of these two surgical procedures has given good results in many hands. The operation has the advantage of being a relatively simple one. The method of Davis and Kanavel has only just been published, and very few cases have as yet been so treated.

Local Measures.

Since cold is, in most cases, the exciting cause of an attack of Raynaud's disease, it is important for the patient to wear appropriate clothing, especially in the winter time. More than the usual amount of underclothing is required in a bad case, and thick gloves made of a non-conducting material should be worn out of doors. They should not be tight enough to impede the circulation. Care must also be taken to keep the feet warm and free from damp. It is better to wear two pairs of thin socks, one over the other, than to wear a single pair of thick socks, because the air between the two layers acts as a non-conductor. Crêpe rubber soles on walking shoes are valuable in keeping out the wet.

Since heat as well as cold may bring on attacks, water for washing should be approximately at blood heat. An attack may sometimes be avoided in a young and vigorous subject by getting him to take a sharp walk, and by friction of the hands. Severe cases should stay at home in a warm room in cold weather. Friction of the hands is valuable, but if they are too painful for this it is still of value to rub the parts in the neighbourhood. Friction may also be combined with hydrotherapeutic methods, such as alternate hot and cold douches to the hands and feet.

In applying galvanic electricity the hands or feet should be put in warm salt water, and the negative pole placed in the bath. The positive pole is either applied directly to an unaffected part higher up, or to the neck, if both hands are affected, and in the bath. The strongest current that the patient can bear should be passed, and it should be frequently reversed. The patient should make voluntary movements of the hands under the water, and the treatment should be continued until the part becomes red. Finally the limbs are dried and well rubbed. High frequency and diathermy may also be of value.

Where gangrene has set in the parts must be treated on surgical principles. Since the gangrene is dry there is not much fear of infection, and dry dressings of boric lint or unmedicated sterile dressings should be employed. The hand may be kept for a time in a sling, and splints may be required. An oxygen bath, made by placing the limb in a wide mouthed rubber bag and filling it with oxygen, is a valuable method of treatment, not sufficiently employed. The mouth of the bag must be bound airtight on to the limb above the affected part. Amputation should never be carried out unless the whole end of the limb is becoming gangrenous. At most, bits of dead tissue may be snipped away with scissors. It is remarkable what good results are obtained with conservative measures, even when a part would appear to be extensively gangrenous.

Drugs.—Iodine or thyroid—the tolerance to thyroid is often great—nitrites, and nitro-glycerine may be administered. Ung. meth. salicylate, linimentum belladonnæ, and iodex may be applied externally. Warm fomentations—not too hot—are also of value. Where there is much pain it has long been customary to add opium to the fomentation.

Conclusion.

To sum up, in the milder cases simple local measures, such as rubbing the hands, bathing them alternately with hot and cold water, and wearing gloves, accompanied by large draughts of normal saline in the early morning, may be successful; but in the more severe cases, especially when gangrene threatens, the complete Einhorn treatment should certainly be adopted, and the oxygen bath used as a local measure.

PROBLEMS OF MENTAL DEFICIENCY.

CONFERENCE OF THE CENTRAL ASSOCIATION FOR MENTAL WELFARE, DEC. 2ND–3RD, 1926.

(*Concluded from p. 1236.*)

AT the afternoon session on Friday, Dec. 3rd, Sir ARCHIBALD BODKIN took the chair and opened a discussion on

ENCEPHALITIS LETHARGICA AND ITS AFTER-EFFECTS.

He said that the importance of this mysterious disease could not be exaggerated. Not infrequently individuals suffering from its after-effects came into conflict with the law. It was clearly necessary that the law should be well defined, based upon well-known rules and administrable, but when it dealt with responsibility its hard and inelastic principles should be qualified so as to march level with the advance of skilled medical knowledge. He thought that the provisions of the Bill now before the House would help magistrates to deal with these cases more properly and more humanely.

Dr. A. F. TREDGOLD confined his remarks to the mental and social aspects of the disease. He quoted the official figures, showing that encephalitis was a prevalent disease; 5039 cases were notified in 1924 and 2635 in 1925, and undoubtedly many cases went unrecognised owing to the extreme diversity of clinical signs and the wide variations in severity. He had known cases reasonably diagnosed as influenza, cerebral tumour or hæmorrhage, chorea, epilepsy, hysteria, melancholia, confusional insanity, sunstroke, infantile paralysis, myasthenia gravis, multiple neuritis, and appendicitis. The disease might bring the patient into a grave condition in a few moments or never show any serious symptoms at all. Yet the mildest cases might be followed by the gravest physical and mental changes, including Parkinsonism, various forms of paralysis, and mental changes with or without delinquency. Statistics relating to the proportion of patients suffering from mental disorder during the acute stage, or as sequelæ to the illness, were very imperfect. The Board of Control had cognisance of 200 cases at the end of 1925; about half of these were below the age of 20, and about one-half of them remained unimproved. Many more cases were dealt with in Poor-law institutions. In the County of London alone there were hundreds of school-children whose mental functions had been seriously affected.

Delinquency.

There was abundant evidence that delinquency occurred in a large number of patients, much more in children than in adults. There might be little intellectual impairment beyond a weakness of memory and attention, but the whole disposition and moral nature were profoundly altered. The patient seemed to have lost all self-respect, wisdom, and moral sense. A child whose behaviour had previously been irreproachable would become a veritable little fiend. Many of them were indistinguishable from moral imbeciles. In a few cases the function of control was chiefly affected, and the child knew and felt he had done wrong, but was unable to stop his acts. The change might supervene immediately on the acute stage of the illness or after an interval of some months.

Pathological Basis.

There were certain marked changes found post mortem. The blood-vessels of the meninges, the grey matter, and the basal ganglia were engorged, and often there were many small hæmorrhages into membranes and brain-tissue and calcification of the vessel walls. Œdema was marked, sometimes so

extensive as to "waterlog" the whole brain. The nerve-cells were in various stages of disintegration, and clearly could not function properly. Where the frontal area was waterlogged lethargy would result; if the œdema were less severe there would be mental confusion, disorientation, false ideas, and excitement. When an impairment of function of the cells remained after the acute attack the result was varying degrees of intellectual weakness, loss of control, alteration of character, and misconduct. The type of lesion left by the encephalitis, the inherent nature of the child, and the extent to which it had acquired control over its innate antisocial propensities through training and home environment, were all factors which determined the form of the mental after-result. There was evidence that some cases gradually recovered, but in a considerable proportion the sequelæ would probably be permanent.

Mental Defect and Encephalitis.

It was wise to allow a reasonable time for improvement before certifying under the Act, and this raised a very important administrative problem. Only a few could be sent to special schools, and there were many in urgent need of special establishments, such as the one recently started by the M.A.B. Prison was worse than the asylum or the institution for defectives. Provision should also be made for investigation and report before sentence upon such cases when they came before the courts.

Dr. F. C. SHRUBSALL related the symptoms and history of the present epidemic, and estimated the proportion of cases in which sequelæ occurred as roughly 30 per cent. of those notified. Out of 193 cases which had been followed up in London, 48 showed impairment of sleep, 24 had paralysis, 22 had twitchings, tremors or fits, 12 had ocular symptoms such as squint, 47 showed impairment of intelligence, and 96 changes of conduct. He emphasised the danger to the public, and the necessity in all cases of encephalitis, whether epidemic or not, of taking immediate action to secure careful treatment and to avoid any irritation due to clashing of personality in the home. The stage of irritation and lack of concentration demanded considerateness combined with uniform and consistent control. Parents were only too liable to overlook this phase and let the child discover that he could get what he wanted by rebellious conduct. Directly the acute phase was over, parents might pet the child overmuch and laugh at fits of petulance; a little later they would chide him severely for just the same thing. The child unconsciously resented this change, and so on a basis of increased irritability there would be built up a superstructure of neurosis. Usually mental deterioration and growth went on simultaneously, so that the only obvious sign at first would be the slowing down of the rate of growth, coupled with return to a more infantile form of emotional reaction. As a rule some mental faculties were considerably retarded or disordered, while others were little affected, so that there was great variability. In adults the mental disorder was more obvious. Medico-legally the position of the post-encephalitic, in relation to responsibility, more closely resembled that of the insane than that of the ament. To him the excuse of "irresistible impulse" might be more justly applied than to any other class of persons. In some cases they could foresee the consequences of their act, but simply did not wait to reflect; in others they made no effort to control their actions. They wished to occupy the centre of the stage at all costs. Many of them reacted satisfactorily to steady discipline. He regarded encephalitis lethargica as one variety of some general underlying disease of which epidemic influenza might be another type, the same causes leading to both. Possibly the same infective agent could cause different symptoms in other individuals, just as, conversely, encephalitis could be caused by many different infections. The post-encephalitic moral delinquency resembled what happened to everyone after a bad cold: they were like "bears with a sore head," but for some hours only.

Discussion.

Dr. E. MAPOTHER said that to offer a woman a lifelong separation from her husband and children was not an ideal solution. Many encephalitic patients had committed suicide, and a number of them might have been saved by encouragement. Among the many difficulties that beset the whole problem were the obscurity of the onset of the disease, and the lateness of the onset of the sequelæ. Diplopia was becoming less common as a characteristic feature, and the attack less easy to identify. Symptoms, in his opinion, might appear up to four or five years after the first attack. The appropriate use of existing arrangements was more likely to solve the problem than special institutions, which could not be properly adapted to deal with all the varied sequelæ. Encephalitics needed the same measure as mental patients—the voluntary admission into mental hospitals. It was difficult to get them sent there, because to regard an individual as a mental case a magistrate wanted evidence of disorder of intellect, which was exactly what these cases did not show. Our ideas on criminal responsibility needed revision, and would not obtain it until every first offender was seen by a doctor before sentence.

Dr. W. R. K. WATSON said that the marked case of encephalitis was not responsible for his acts, but there were all degrees up to complete responsibility, and it was very hard to know where to draw the line.

Mr. J. W. FLINT and MRS. A. L. SHAVE pleaded for special accommodation for these cases, to save them from the stigma of being certified and removed to institutions under the Lunacy or Mental Deficiency Acts.

Mr. R. W. BLACKIE said that only one of the many cases before the Birmingham magistrates had been certified under the Mental Deficiency Acts, and none had been put in prison. He asked if these children could not be specially earmarked and watched when in mental deficiency institutions, with a view to liberation after a few years.

Dr. E. H. T. NASH spoke of the difficulty of diagnosis, and pointed out that the severity of the acute stage was no criterion of the severity of the sequelæ.

Dr. F. D. TURNER assured the meeting that there was no danger of post-encephalitic cases being wrongly retained in mental deficiency institutions, emphasising the fact that these children are "possessed of the devil." He suggested that they were probably best in ones and twos amongst other children, and not massed in a special institution. He had found that they often deteriorated physically as they improved in conduct.

Dr. TREDGOLD agreed with Dr. Turner that post-encephalitic cases earmarked themselves, and repudiated the suggestion that they could ever be herded unclassified for life in a modern mental deficiency institution.

POST CERTIFICATE SCHOOL FOR MIDWIVES.—Mr. Neville Chamberlain has consented to open the new building in connexion with the Post Certificate School in Camberwell on Feb. 8th, 1927.

THE Papworth Press, Cambridge, announce the forthcoming publication of "The Significance of Temperature Variations in Tuberculous Disease," which is, according to the subtitle, a study in continuous and quasi-continuous temperature records of man and animals in health and disease. The book is a reissue of papers which have appeared in THE LANCET under the signatures of the late Sir G. Sims Woodhead and Dr. P. C. Varrier-Jones, together with the results of Dr. Varrier-Jones's further experiences at Papworth. It is unique in that it has been printed and bound, and will be published by, the consumptive ex-patients in the printing department of the Papworth Village Settlement.

REOPENING OF THE WELLCOME MEDICAL RESEARCH BUREAU.

RESEARCH AND CITIZENSHIP.

ON Dec. 8th Mr. Neville Chamberlain, the Minister of Health, reopened the Wellcome Bureau of Scientific Research, which has been reconstructed and enlarged. The building is in Endsleigh-gardens, London, N.W., and offers excellent facilities both for research and instruction. Individual workers who wish to follow any particular line of investigation are given accommodation and help in their studies, whilst an immense amount of information is made available to the medical and allied professions by means of a specialised reference library and a comprehensive museum.

The Bureau was founded in 1913 by Mr. Henry Wellcome, and is affiliated to the other institutions in London which bear his name. It contains 12 research laboratories, whereinvestigations may be made in all branches of pathology and parasitology, but especially in tropical medicine and hygiene. The Museum, which is arranged in 20 small halls, aims at a general survey of disease, and is open to all medical men and students, and also to laymen introduced by a registered medical practitioner. Teachers are invited to make full use of it for purposes of demonstration, and arrangements can be made for them to bring classes of students. Much of the success of the exhibition, as Dr. S. H. Daukes, the Director, points out, is due to the coöperation of medical men in various parts of the world, and it is hoped that their help will continue so that the Museum may become even more complete.

WELLCOME MUSEUM OF MEDICAL SCIENCE. [*Copyright.*

Owing to the unavoidable absence of Mr. Wellcome in America, the proceedings were opened by Dr. C. M. Wenyon, Director-in-Chief of the Bureau, who introduced Mr. Chamberlain. In formally declaring the Bureau and Museum reopened, Mr. Chamberlain referred to the extraordinary acceleration of medical progress in comparatively recent times. The reason of this acceleration, he said, could perhaps be found in the fact that knowledge was now so rapidly spread from one part of the world to another. In the old days a new discovery seldom reached much beyond the immediate environment in which it was made, but to-day every advance was immediately registered and imparted to everyone who was interested throughout the world.

The Museum which he was to reopen, continued Mr. Chamberlain, was of unique and remarkable character. The labour brought by Mr. Wellcome to its perfection must have been inspired by a belief in research and education as the two greatest factors in helping mankind to overcome their infirmities. It was over 30 years since the Research Laboratory in Physiology was founded, and that had been followed by the Laboratory of Chemical Research. Much more recently Mr. Wellcome had instituted the Entomological Field Laboratory, and now all these various institutions, together with the Historical Medical Museum, were affiliated to the Medical Research Bureau.

This building, then, was the headquarters of the whole system of scientific research in which Mr. Wellcome had interested himself, and contained, also, the means of spreading and promoting education amongst students and teachers. The method of instruction adopted was pictorial, and the drawings, paintings, photographs, models, and actual specimens must present a picture of a vividness and impressiveness which perhaps could not be excelled by any other method of demonstration. The collection was, he thought, unparalleled in any medical school — certainly in this country, and probably in the world. It dealt not merely with the diseases of temperate climates, but also with those of the tropics, and exhibited their causes, symptoms, treatment, and prevention with a completeness which was altogether unexampled. If, indeed, the great advances in medicine and surgery were largely due to the spread of knowledge from the one to the many, then everybody must agree that Mr. Wellcome was a great public benefactor in making available this epitome of all that science had hitherto achieved in this domain.

Sir Walter Fletcher, F.R.S., Secretary of the Medical Research Council, then delivered an address on Research and Citizenship, in the course of which he said that the Bureau and its associated laboratories, considered as a single organisation, had already taken its place as one of the important centres of medical research work in this country. Almost from its beginning original and fruitful scientific investigations had been conducted within its laboratories, and the results had been freely published in the technical scientific journals. This successful work, past and present, was due to the able men who by aid

of this organisation had found their opportunities. To his mind the special interest of the Wellcome organisation, looking at it from a national point of view, was its origin and the particular mode of its financial support. They illustrated some real problems of the economics of research work and of its place in national life. For research it was necessary to have leisure and materials. The history of scientific research, as known to-day, had been worked out in highly organised capitalistic communities. In this and other countries it had, in fact, depended during the past centuries not upon any enlightened and far-sighted support given to it by the general community, but upon the accidents of the distribution of wealth—upon private patronage, upon the endowments of universities, and sometimes upon the personal possession of wealth by the investigator. The nineteenth century had come and gone without making much change in this system of *laissez faire*—in spite of the great wealth of the country and the rise and development of industries which had owed their very existence to science. Accident was allowed to decide whether the right conditions should be found for investigation, and when discoveries turned up they were only slowly utilised. The land-owning and governing class showed what Gibbon described as "the proud ignorance so dear to a polished people." The new rich grasped at the immediate opportunities of wealth and became practical men who, as Disraeli reminded them, were practical in that they practised the mistakes of their ancestors.

As the present century opened, continued Sir Walter Fletcher, our relative decline in trade, and the capture by other countries of industries native here, had begun to teach the lesson—a lesson driven home during the war. This first quarter of the new century had seen great changes, and during the same period the great manufacturing firms had increasingly realised that not only their success but their existence depended upon the progressive work of discovery and its application. The manner in which business firms established and used their research departments varied very widely. Commercial enterprises had forwarded the development of scientific work in three ways: (1) Private fortunes made in commerce had sometimes, though far more rarely than might be expected, been devoted to the support of research work. (2) Commercial profits might be used to promote research; the firm might directly support scientific research work relevant to the objects of the business, the results gained being exploited for private interests. This kind of work was not likely to encourage fundamental discoveries or to attract and keep men capable of making them. Lastly (3), a few firms had adopted the plan of supporting scientific work and leaving their workers as free to follow their own line and to publish their results as men in any University laboratory. This method was not exclusive of the former method, and might be additional to it. The Wellcome Bureau and laboratories were supported under this system, and the firm which controlled them might take legitimate pride in the results given to the world.

Going on to speak of the Museum and Library, Sir Walter Fletcher described them as forming together a sumptuously illustrated text-book. In chosen parts of the subject a student might learn more from a quiet hour in one of its divisions than he was likely to gain from any ordinary formal lecture of the schools. The Museum also had a large usefulness for the instruction of intelligent laymen. A former Minister of the Crown, now in high administrative office overseas, had told him that a visit paid to the Museum had given him his first really vivid impression of what scientific work had done and might still do for the peoples of our Empire. It had aroused for the first time his enduring sympathy and interest. The work of science could only have its full effect in the welfare of the people by the steady growth among the general body of citizens of sympathy with its methods and faith in its powers. It ought to be a proper part of citizenship to understand something of the difficult path the pioneer investigator had to follow, and to see something of the processes by which a discovery came into practical application. Only the dull or uninformed could enjoy material benefits without caring to know anything of the paths by which they had come and of the hands that gave them. Such knowledge, in one field of science, was made easy of reach by a Museum like this. Material benefits, however, did not form the highest gain received by the pursuit of natural knowledge. The work of the Bureau, Laboratories and Museum was twofold—that of increasing "God's honour and bettering man's estate."

At the conclusion of the address, Sir John Rose Bradford, President of the Royal College of Physicians of London, proposed a vote of thanks to Mr. Chamberlain and Sir Walter Fletcher. This was seconded by Sir John Bland-Sutton, Past-President of the Royal College of Surgeons of England, and was carried with acclamation. Sir James Kingston Fowler proposed a vote of thanks to the Founder, which was seconded by Prof. T. R. Elliott, and in Mr. Wellcome's absence was acknowledged by Dr. Wenyon.

MEDICINE AND THE LAW.

Colonel Kynaston's Appeal: Remarkable Sequel.

THE prosecution of Lieut.-Colonel Kynaston, R.A.M.C. (retired) under the Dangerous Drugs Act, 1925, has had a sequel which must be almost unique. The Act of 1925, it appears, is not yet in operation, and, presumably, other persons who have been convicted thereunder will now be relieved of the penalties imposed upon them. Lieut.-Colonel Kynaston, it will be recalled, was lately convicted at the Central Criminal Court of aiding and abetting a patient (whom he was treating for catarrh) to obtain medicinal opium contrary to the Act (the accused being no longer a registered practitioner). His defence, so far as a newspaper summary gives a fair indication, consisted of two main points; one of these was irrelevant and the other was wrong as a matter of law. His irrelevant point was that his name had been wrongly erased from the Medical Register and that he was unjustifiably deprived of his qualifying degrees by the colleges which had conferred them. His other main point was that he was still qualified if not still registered, and that thus, if the enactment under which he was prosecuted used the words "duly qualified medical practitioner," he was still within its terms. This contention was untenable in law because Section 34 of the Medical Act of 1858 makes it clear that the words "legally qualified" or "duly qualified" medical practitioner, if used in any Act of Parliament, mean a practitioner registered under the Medical Act. Colonel Kynaston, having been fined £10, took his case to the Court of Criminal Appeal, where he raised various points which, apparently, left the judges unmoved. Then there was a dramatic surprise. Counsel for the prosecution got up and announced that he had just discovered that the 1925 Act was not yet in force. It was (under Subsection (3) of Section 7) to operate on such date as His Majesty should by Order in Council appoint. No Order in Council had ever been made, and counsel's effort to support the conviction as justified under the previous law was not permitted by the court. The Lord Chief Justice made some pleasant observations upon the ludicrous situation thus disclosed, and the case terminated inevitably with the quashing of the conviction. Lord Hewart stated that the appeal had no real merits, but, as the Act under which the prosecution had been conducted was not in force, the proceedings "resembled nothing so much as pulling a bell-handle without a bell at the other end."

The incident illustrates the danger of the modern practice—otherwise found so convenient—of putting masses of legislation on the statute-book with a postponement clause by which a particular enactment does not take effect until the administrative arrangements

are complete and until the Privy Council or some other authority presses the button. Neither side comes out of the case with much credit. The Home Office has stultified itself in a manner unparalleled in that otherwise so shrewd and careful Department of State. Colonel Kynaston escapes on a point which was, presumably, as great a surprise to himself as to everyone else. His offence against the Dangerous Drugs Acts—as has previously been stated in this column—was trivial in the extreme; but the quashing of his conviction still leaves him exposed to the charge of signing a prescription with a claim to degrees which he no longer possesses.

Milk Bottles Filled in Street.

Fines of 20s. each were inflicted by the Brighton justices on Dec. 9th on a milk roundsman and his employer, the former for delivering bottles which had not been filled and closed on registered premises, and the latter for aiding and abetting, or alternatively delivering the milk by his agent. The 1926 Order, under which the proceedings were taken, makes it illegal to fill bottles in the street. In this case Dr. Duncan Forbes, medical officer of health for Brighton, saw the milk roundsman filling bottles in the early morning from a can and capping them with caps which he took from his pocket. The pocket was convenient for holding the caps, he said, when questioned. The man's employer said that so far as he was aware all the bottles were filled before they left the dairy, and that the regulations had been explained to all his employees.

At a session of the Bombay Medical Council held on Sept. 20th the name of Mr. Joseph Michael Pereira, M.B., C.M. Edin., 1894, was erased from the Register, following the Council's decision that he had been guilty of infamous conduct in a professional respect by issuing sick certificates in a case in which he had not been in personal attendance on the patient during the period covered by the certificates. At the same time a practitioner holding Indian qualifications received similar sentence under the Bombay Medical Council. Mr. Pereira's name, it would seem, has not appeared on the Register of the General Medical Council of the United Kingdom.

The Home Secretary gives notice that he has withdrawn from Mr. Frank Allday, L.D.S., of 26, Charing Cross-road, W.C., the authorisation to be in possession of dangerous drugs or to supply them on prescription.

PARIS.

(FROM OUR OWN CORRESPONDENTS.)

Infantile Mortality in Hospitals.

THE high death-rate amongst babies in French hospitals—it has been estimated at 35 per cent.—can be accounted for in several ways. The children come to hospital in so bad a condition that they often die in the first five days after admission. For the most part they are under-nourished and have been bottle-fed; furthermore, they are taken away from their mothers. Naturally enough the mortality amongst those who come into hospital with their mothers and are breast-fed is not so high—perhaps about 26 per cent. Infants stand badly a long stay in hospital, and often end by taking some infection or by wasting away. With the idea of reducing this mortality, Dr. C. Lesné advises that as far as possible children should not be taken into hospital; that more clinics for infants should be set up; and that babies should be treated more at home, assistance being given to the mother by visiting nurses. For those acutely and dangerously ill and those who are quite incurable, treatment in hospital is necessary. There should, however, be more wards into which the mother can be admitted with her child, and wet nurses ought to be provided for those who cannot get their mother's milk. Every child, says Dr. Lesné, should be kept strictly isolated, and there should be a specialist staff large enough and skilful enough to take the necessary precautions against spreading infection from one child to another. The stay in hospital should be as short as possible, and it is wise to have a convalescent home in the suburbs where babies can go if their health is still too precarious for them to be sent out into the country.

Sarcoma of the Œsophagus.

Compared with epithelioma, sarcoma of the œsophagus is a rarity, and it is quite exceptional to be able to diagnose the condition during life. Dr. Guisez, of Paris, reports the case of a man of 54 who had a tumour of the middle third of the œsophagus which caused more or less complete stenosis. Microscopical examination of a portion of the growth removed at œsophagoscopy showed that it was a spindle-celled sarcoma. Radium was applied locally and the tumour rapidly disappeared, so that the patient was able to swallow normally for a period of ten months, after which, however, the sarcoma recurred lower down, and proved less amenable to radium than before.

Dangers of the Geyser.

Dr. Georges Luys has been pointing out the risks of using gas geysers in bath-rooms. There are, he says, two dangers: First, the high content of carbon monoxide in illuminating gas, and secondly, the possibility that products of combustion may escape into the room without being noticed. The geysers may apparently be working well; they produce hot water; there is no smell of gas; yet, nevertheless, a flue may be blocked. It is thus absolutely necessary that geysers should often be inspected to see that they are working properly and that the fumes can escape through the proper channels.

Arsenic and Grapes.

Prof. E. Ledoux, of Besançon, has recently reported some cases of arsenical poisoning due to drinking wine made from grapes which had been treated with insecticide made from arseniate of lead. Care had not been taken to comply with the regulations which forbid powdering of the vines with arsenicals after they have flowered, and the wine in question contained a large amount of arsenic.

Hospital Risks.

No provision is made against occupational risks—infections, accidents, and disease—incurred by the staff in hospitals administered by the French Government. Prof. Mougeot, charged with the duty of examining the matter anew, has reported that all efforts made as yet for obtaining just compensation for accidents have wholly failed, and advises that special legislation should be secured at once.

Observations on the Duodenum.

Dr. Maurice Delort, of Paris, has lately drawn the attention of the Society of Medicine to a special method of radiological examination of a loop of intestine between two points of compression. His work has been done on the normal duodenum. The method consists of stopping, or rather slowing, the flow of duodenal contents by compressing the duodeno-jejunal junction by means of a special abdominal belt fitted with pneumatic pads. Dr. Delort was able to show clear pictures of the distended duodenum, and his technique appears to give the observer an improved chance of drawing conclusions about the condition of the viscus.

Barbituric Derivatives.

Kohn-Abrest and Pissot have reported on an investigation of veronal and other members of the barbituric group of analgesic and hypnotic substances. The toxicity of these compounds, they point out, varies considerably, and depends mainly upon renal function. Veronal, for example, may be given safely in doses reaching 14 g., provided the kidney be perfectly sound, but where renal function is impaired, doses of less than 1 g. may be very dangerous. In determining whether the quantity of veronal and

similar compounds found post mortem suffices to explain why death has taken place, the general state of the patient—and especially the renal condition—must be carefully considered.

The Milk Supply.

The French National Society for encouraging agriculture is proposing to form a committee for improving dairy products and for securing effective inspection of dairies, byres, and establishments. Producers willing to permit inspection will be entitled to obtain higher prices for the milk sold under sanction of the society and also of the Ministry of Agriculture. This plan resembles very closely the plan under which so-called certified milk is marketed in the United States.

The *Syndicat*, or union of French Surgeons, has decided that patients able to pay for surgical services ought not to have free hospital treatment and care, and are drawing up a tariff of fees. They consider that surgeons should be paid directly and without intermediate official relations.

The French Ministry of Labour and Hygiene is investigating the manufacture and handling or radio-active substances so as to devise measures fof protecting those engaged in certain industries.

A centre for mental prophylaxis in childhood, directed by Prof. Roubinovitch, has been established at Vanves, near Paris. Post-graduate classes will be held at the centre.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Synthaline.

AT a recent meeting of the German Society for Diseases of the Digestive Organs and Metabolism Dr. Frank, of Breslau, reported on a derivative of guanidine, called synthaline, which has been shown to produce hypoglycæmia. Its effect is slower than that of insulin, but of a longer duration because of the cumulative action of guanidine. The advantage of the preparation is that it may be administered by the mouth ; the drawback is that the appetite suffers and that sometimes the drug causes vomiting and diarrhœa, though never in a dangerous form. Severe cases of diabetes, especially those in which coma is threatening or the patient is actually comatose, will, as before, belong to the domain of insulin, though by giving synthaline along with it the number of injections may be lessened. Prof. Richter, of Berlin, confirmed the results obtained by Dr. Frank by his experience in 25 patients, and so did Prof. Umber and Prof. Strauss.

Iodised Salt and the Prevention of Goitre.

In Switzerland the administration of iodised salt has proved very useful in the prophylaxis of goitre, and some good results of its adoption in Germany have now been described by Dr. Sepp, a medical man residing in a goitre district in Upper Bavaria. He found that in the local sick club the sick-rate from all causes was little affected by the use of iodine, varying only from 286 to 234 cases a month, but the figures for goitre showed considerable reduction. In the period between the first quarter of 1923 and the third quarter of 1924, 320 of 1789 patients suffered from goitre, whilst in the period between the fourth quarter of 1924 (when the salt was first introduced) and the second quarter of 1926 only 87 of 1743 patients had goitre. The constant decrease is indicated by the fact that in the last quarter of 1923 22·6 per cent. of all the club patients suffered from goitre, whereas this percentage had fallen in the last quarter of 1924 to 7·2 and in the second quarter of 1926 to 3. No case of thyroidism occurred in club patients, as they did not take more iodine than the doses supplied to them, but a number of cases were observed in private practice where patients had, at their own expense, indiscriminately swallowed larger doses of the compound.

Public Health Services.

DOCTOR REFUSES SCHOOL CERTIFICATE.

A CASE of some interest to practitioners has recently been reported in the *Wolverhampton Express*. A parent was summoned by the local education authority for not sending a child regularly to school, and called, as a witness for the defence, the doctor who was attending the child. The doctor is reported to have said that the child had been suffering from pneumonia and whooping-cough, and later had had an operation for the removal of tonsils and adenoids ; he had refused on principle, however, to sign a certificate, as, since education was compulsory, he did not see why parents should be forced to pay for a medical certificate. In making this apparently reasonable objection, the doctor does not seem to have taken into account the legal position of the local education authority. Section 42 of the Education Act, 1921, enacts that it is the duty of the parent of every child to cause the child to receive efficient instruction in educational subjects, and Section 43 states that it is the duty of the local education authority to see that this duty is performed by the parent. The onus for presenting the child at school rests, therefore, on the parent, and in the event of a child not attending school the parent must convince the local education authority that his consent for the non-attendance of the child has been reasonably withheld with the bona fide intention of benefiting the child. The most effective proof of bona fides that a parent can produce is a medical certificate of unfitness.

Although the statutory obligation of the authority is clear, action is not taken without sufficient cause, such as the prolonged absence of a child from school and the repeated refusal of a parent to produce a medical certificate or to present the child for examination by the authority's medical officer. In this case the authority's representative, in the person of the attendance officer, had called eleven times at the child's home, and no proof of the child's unfitness to attend school was produced. The authority, therefore, could hardly do otherwise than have the case settled in court.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some of the statistics for 1925 of three cities :—

Name of city.	Estimated mid-year population (R.-G.).	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.	
			All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Heart disease.	Infant mortality.	Maternal mort. from childbirth.
Sheffield ..	526,900	17·7	11·5	0·99	1·32	2·3	1·5	84	4·9
Hull	297,300	21·8	13·2	1·26	1·16	2·9	1·2	93	4·8
Cardiff ..	227,300	20·6	12·8	1·53	1·09	2·3	1·7	92	4·5

Sheffield.

Dr. F. E. Wynne records an outbreak of small-pox during the last quarter of the year, which originated with two unvaccinated boys who contracted the infection while staying in Middlesbrough. Both boys had mild attacks, for which no doctor was called in, and which were regarded as chicken-pox. One of them returned to school, and other cases arose at the school. There were 44 cases up to Dec. 31st, all traceable to the two original ones. (The patients were none of them protected by vaccination—i.e., they were either unvaccinated or adults vaccinated in infancy only.) Although up to the end of the year there were no fatal cases, several of the victims were

dangerously ill, and will be scarred and disfigured for life. This, says Dr. Wynne, disposes of the theory that the mild type of small-pox is a new disease and always breeds true. Referring to the exceptional industrial depression and unemployment, Dr. Wynne points out that there has been no set-back in the public health, and attributes this to the much better organisation of relief under modern conditions. He thinks, however, that if in the immediate future there is a general resumption of employment there will be an unheard-of loss of time and wages as the result of industrial fatigue among men who are out of training, and this will be reflected in the sickness-rate of the country during the first period of resumption.

The Sheffield system of sewerage disposal by bio-aeration, devised by Mr. Haworth, is being extended. Five years ago there was only an experimental tank in operation. Now 8 to 10 million gallons of sewage are being treated daily.

There was a fall in the notification of encephalitis lethargica after the severe outbreak of 1924, when there were 337 notifications and 40 deaths. The notifications in 1925 numbered 54 and the deaths 21. During 1925 Sheffield had the lowest death-rate from pulmonary tuberculosis of any of the 17 provincial towns with populations exceeding 200,000, and for all tuberculosis it was a close second to Bradford. Dr. Wynne thinks that the silicosis regulations have done much to reduce the mortality in the various classes of grinding and abrasive industries. Nevertheless, he would like to see the abolition of the little, dark, insanitary "wheels," and the substitution of well-equipped large factories. During the year ending March 31st, 1926, the number of houses completed was the largest in any year since the war—namely, 2178, of which 1361 were erected by the corporation. The overcrowding in the city is still deplorable, and there is a waiting list of 2822 for municipal houses. The scheme for the conversion of privies into water-closets made unusually rapid progress. Nearly 2000 were converted.

Dr. John Rennie, the chief tuberculosis officer, reports that the dispensary is being well used by the medical profession for diagnostic purposes. In over 70 per cent. of the notified cases the patients were sent to the dispensary prior to notification. Thus a large proportion of cases are being discovered at an early stage. The X ray apparatus has proved invaluable, and 1726 skigrams were made during the year. There were 1356 contacts examined. The names of all children of school age who are known to have been exposed to infection in their homes are supplied to the school medical officer, in order that they may be kept under observation during their school-life. In six cases tubercle bacilli were found in the sputum of school-children. The surgical tuberculosis officer, Dr. C. Lee Pattison, gives a table showing that out of 104 deaths from non-pulmonary tuberculosis 46 were due to meningitis, 21 to intestinal tuberculosis, 10 to spinal disease, and only 4 to disease of other bones and joints. Dr. Pattison also reports that the cases are being brought under treatment at an earlier stage. Thus, as superintendent of the Rivelie Hospital (run on the same lines as Alton), he finds that the average duration of stay was only 324 days as compared with over 700 days during 1919 and 1920. Also during the first few years after this hospital was opened there were always about 50 patients waiting for admission, whereas now 30 of the 130 beds are not needed for Sheffield children, but are used, with the sanction of the Ministry of Health, for children from outside areas. Dr. Pattison finds that ultra-violet light treatment causes definite improvement in enlarged cervical glands, and that most cases of lupus show improvement, some of them to a very marked extent. Selected cases of bone and joint disease improved "but in many the cure of the patients did not advance more rapidly than that of those treated by other methods."

The veterinary inspector, Mr. J. S. Lloyd, reports that of 909 samples of mixed milk coming in to the city by road or rail 91, or 10 per cent., were tuberculous. In following up the samples 100 farms were visited. At 57 of these farms 59 tuberculous udders were found. At the remaining 43 farms no tuberculous udders were found, and the subsequent control samples of the mixed milk proved to be negative. In most of these 43 farms cows had been sold during the period of waiting for the result of the biological test. Within the city there are 2539 stalls for milch cows, and in these stalls 20 cows with tuberculous udders were found during the year. Only three of the tuberculous cows were lost sight of, the remainder were slaughtered. Mr. Lloyd again emphasises the value of the direct microscopical test. Thus during 1925 37 country cows and 10 city cows were found to be suffering from tuberculosis of the udder by the microscopical examination alone. These 47 cows were removed from the milch herds and slaughtered without having to wait for the biological test. The mixed milk of the herds was, therefore, freed from infection about a month earlier than in those cases where resort had to be made to the biological test.

Hull.

Dr. W. Allen Daley reports a big spurt in the work of getting rid of the privies and pail closets in the city. It was begun in 1921 with the conversion of 183. In the four subsequent years the numbers converted have been 594, 1598, 5163, and 8555. Over 16,000 of the 41,000 to be dealt with had been converted up to the end of 1925. The Health Committee employ a whole-time salesman, whose duty it is to find customers for the night soil, which is sold for manure to farmers, market gardeners, and allotment-holders. Over half of this material is carried into agricultural areas outside the city in the carts in which it is collected.

Hull Fair is an annual institution that owes its inception to powers contained in the first charter granted to the town by Edward I. in 1299. It lasts for six days in October, on a site covering 13½ acres, and is visited by tens of thousands of people. In 1925 there were 245 vans and four tents on the fair ground, occupied by 566 adults and 204 children. The sanitary inspectors make daily visits, and temporary sanitary conveniences are provided. No overcrowding was discovered, and the only known cases of sickness were a case of pneumonia and a case of pleurisy. Hull had the first municipal crematorium, opened in 1901. During the last five years cremations have averaged about 44.

In 1920 it was estimated that 5000 houses were needed to meet the arrears of the war years and the years before the war. Since that date 2157 houses have been erected, of which 1475 provide for the increase of the population since 1920. As, however, many houses have been demolished in these years, arrears have only been reduced by 282. The corporation have three housing estates on the outskirts of the city, comprising 328 acres, of which over 20 are outside the boundaries. At the end of 1925 on these estates 1032 houses had been completed, 510 were in course of erection, and contracts for 498 had been let. Two steel (Braithwaite) houses have been put up on the West estate, and contracts have been let for 442 houses of special concrete or concrete and steel frame construction. If the present acceleration in the rate of building is maintained the shortage should be eased in a few years, but it may prove necessary, says Dr. Daley, to build houses of a less costly type. Over 80 per cent. of the houses in the city are of the working-class type, which Dr. Daley divides into the artisan type (43 per cent.), the inferior terrace type (33 per cent.), and the slum houses (4 per cent.). The privy conversions have greatly improved the second class . . . "as under the old system the contents of the privy had to be carried through the kitchen, often during the breakfast hour." The slum houses include about 500 of the back-to-back type, and are old and poor in structure. Demolition is the only remedy. Owing to the shortage of houses no further action has been taken with regard to the seven unhealthy areas covering about 28 acres and comprising 1784 houses, which were reported in 1919. One area has been

proceeded with, and will displace the 721 occupants of 182 houses, for whom the provision is being made of 145 "parlour" houses on the East Hull estate, two miles away from the area. Owing to the unlikelihood of the dispossessed tenants taking up houses so far from their work, a scheme is now under consideration for the erection of three blocks of four-storey flats on a portion of the original area.

There is one retailer of Grade A milk and one licensed dealer in pasteurised milk. In September it was decided to get Grade A milk for the two city hospitals from a producer in the East Riding. Twenty-seven samples of milk were examined for tubercle, and two gave a positive result. During 1925 there were 22 notifications of encephalitis lethargica and 20 deaths. An outbreak of small-pox occurred in the latter part of the year and continued until March, 1926. There were 59 cases in 1925 and 35 in 1926. The disease was of a mild type, and caused no deaths. The source ofthe original infection was never discovered. The tuberculosis training colony, from its inception in 1919 to the end of 1925, trained 108 Hull residents (105 men and 3 women). Of the 108, 76 were at work at the end of the year, and 40 of these at the vocations for which they had been trained. On the other hand, of the 12 Hull men sent to other colonies to be trained under the Government scheme, only one is working at the occupation for which he was trained. The scheme for the prevention of crippling has received much consideration, and as a result six beds will be taken at the Yorkshire Orthopædic Hospital at Kirkby Moorside for a trial period of six months; the residential beds at the school for cripples will be increased from 18 to 24, and non-tuberculous cripples will be admitted at any age from 2 to 16; and a clinic under the direction of an orthopædic surgeon will be established as a clearing-house. The figures for venereal disease indicate that much gonorrhœa in women is untreated. Thus during the last two years there have been about two cases of syphilis to three of gonorrhœa among males, whereas among females there are two cases of syphilis to one of gonorrhœa. When the new clinic has been completed there will be a separate session conducted by a woman doctor for women and children innocently infected. Midwives attended about 64 per cent. of the births, and sent for medical aid in 22·7 of their cases. Preventive midwifery is making progress. Thus at the clinic conducted by Dr. Ethel Townend there were 602 new patients. Forty-six malpresentations were corrected by external version, 12 cases of disproportion were sent in to the maternity home for induction of labour, and two cases of severe pelvic contraction were sent to the Hull Royal Infirmary for Cæsarean section. On the other hand, the unsatisfactory results of emergency Cæsarean sections was demonstrated by five such cases admitted to the maternity home. Two of the mothers died and four of the children were stillborn. In an appendix Dr. Katherine Gamgee submits a report on two years' working of the artificial light clinic. Over 300 cases were treated, and Dr. Gamgee's conclusion is that in a large industrial area such a clinic should prove of very great value in the treatment of rickets, malnutrition, and anæmia of children of all ages, for the prevention of early disease in young children, and for dealing with children who are not making progress at the ordinary centres.

Cardiff.

Dr. Ralph M. F. Picken thinks that the relatively high standard of health maintained during this period of trade depression is due to the efforts of the guardians and to the unemployment insurance funds. Referring to the steadily increasing mortality from cancer he thinks that the increase is a real one in Cardiff. The local investigation as to the end-results of operations for cancer of the breast confirms the general conclusion that results are excellent, given early diagnosis and early operation. Cardiff holds a bad position for tuberculosis, and had the highest rate from pulmonary tuberculosis among the 17 large provincial towns during 1925. Dr. Picken emphasises the fact that the number of beds for advanced cases is inadequate. He also points out how much more satisfactory it is to prevent tuberculosis than to attempt to cure it when it has become manifest. Thus while 63·6 per cent. of the cases of pulmonary tuberculosis notified in 1925 were alive at the end of that year, only 7·4 per cent. of those notified in 1915 and still known to the department have survived. Open-air schools, open-air teaching, more attention to physical culture and the teaching of hygiene in the schools, more seaside homes for debilitated children, and the use of artifical sunlight during the winter are some of the preventive measures which he advocates. At the centres for venereal disease 34 per cent. of the patients ceased to attend before the final tests for cure. As might be expected, the default was highest among the seamen—namely, 43 per cent. A statement shows where 494 seamen contracted their infection. Of the 80 cases recorded against Wales 73 were infected in Cardiff, 49 were recorded against England, 25 against the Argentine, 73 against France, 15 against India, 21 against Italy, 29 against Spain, and sc forth; but the record is rather a measure of the amount of trade than of the prevalence of venereal disease in those countries. The new clinic for women and children was opened in the last week of 1925, and the attendances up to date showed that it is serving a section of the public not provided for hitherto. The antenatal clinic, under the joint management of the health department and the infirmary, became firmly established in December, 1924, and the other antenatal clinic has been transferred to more satisfactory premises. The new cases attending increased from 325 in 1924 to 815 in 1925, and the quality of the antenatal service has improved in proportion to the improvement in premises and equipment. The corporation now pays £1200 per annum to the maternity branch of the Royal Infirmary instead of paying for individual patients. During 1925 the cases admitted to maternity beds numbered 461; 349 were sent through the antenatal clinics, 48 complicated cases were sent by general practitioners, and there were 64 other Cardiff cases. On Nov. 3rd the new orthopædic clinic was opened. The 130 crippled children under 5 years of age known to the department comprise 54 crippled by poliomyelitis, 25 by congenital malformations, and 32 by rickets.

The proportion of houses in Cardiff occupied by members of more than one family is about 28 per cent. A sample of 3112 of such houses showed that in 402, or 13 per cent., there was mixing of the sexes over 13 years of age—a rather high age—in sleeping-rooms (exclusive of married couples). If the same proportion holds for all the 11,000 multiple tenant houses, the number sex-overcrowded amounts to 1420. Sex-overcrowding is, however, not confined to multiple tenanted houses, and it is estimated that in the city at present there are about 2000 sex-overcrowded houses.

There were 55 samples of milk examined for tubercle bacilli, and two gave a positive result.

Dr. Picken shows that the hospital accommodation of the city is inadequate. The voluntary hospital accommodation amounts to 483 beds, with prospect of immediate extension to 515, and ultimately to 615. This, however, includes 74 beds at the Seaman's Hospital and 34 at the Prince of Wales's Hospital, to a diminishing extent available for Cardiff cases. The guardians propose to erect a new hospital at Llandough with 408 beds, capable of extension to 952. Dr. Picken points out that the new hospital will, sooner or later, become a municipal hospital, that provision should be made for paying patients, that it should ultimately form an integral part of the medical school, and that a very large proportion of the patients will be of special types and cannot satisfactorily be treated in large blocks of wards of uniform pattern. He urges that the new hospital should be thoroughly up to date in every respect, and that a well-equipped laboratory should be provided at the outset.

REPORTS OF SCHOOL MEDICAL OFFICERS.

* Not given. † Excluding dental defects and uncleanliness.

Shrewsbury.

Dr. A. D. Symons, who took up his duties in September, 1925, reports that, so far as he has been able to judge, the health of the Shrewsbury children is satisfactory, as is certainly suggested by the small percentage of defects found during routine examination; but he has lost no time in pointing out the need for further effort. The inadequacy of the present nursing staff and of the present dental arrangements is clearly shown, as is the necessity for a definite scheme for treating tonsils and adenoids and for a class of mental defectives. He supplements oral advice given at medical inspections by the issue of leaflets written in clear and simple language, on the eradication of nits, the necessity for early treatment of squint, the prevention of dental caries, hygiene of the air passages, and food for growing children. Copies of these pamphlets are given in the report. The school clinic, which is open every morning except Saturday, has been reorganised, and has become a real centre for help, advice, and treatment. Many sound and practical suggestions contained in the report will soon be carried into execution—e.g., the provision of slippers in schools to prevent children getting chilled by wet and sodden boots.

Eastbourne.

Dr. W. E. Willoughby includes in his report a summary of the work done by the organiser of physical training; this shows a marked improvement in the condition of many malformations. There has been a big fall in the school population since 1912, owing to the low birth-rate in 1918–19—the largest decrease being in the infants departments. This decrease may make it possible to close certain schools where hygiene is defective. The facilities for treatment and for the care of abnormal children are good. There are clinics for ophthalmic, and throat, nose, and ear examinations, for dental treatment, and for inspection and treatment of malnutrition and tuberculosis. There is an open-air school and a special school for mental defectives, and although there is not yet an orthopædic centre, much good work is done at voluntary clinics for massage and electrotherapeutics. The secondary school-children showed a higher percentage of defects than the elementary school-children, while in the voluntary—e.g., continuation—schools the coöperation of the parents was much poorer. Dr. E. H. B. Coghill gives a short account of his treatment in a few bad stammerers.

Stockport.

The assistant school medical officer, Dr. W. H. Rowell, presents this report in place of the late Dr. A. G. Jenner. Reinspection in nearly half of the elementary schools was not carried out owing to illness among the staff. Many improvements have been made in the sanitary conditions. In some schools trough and privy closets have been replaced by separate flushing conveniences; in others lighting and ventilation have been improved, while playgrounds have been formed and tar-paved in four schools. Dual desks and tables are replacing antiquated furniture. The authority's schemes provide for treatment of minor ailments and dental defects; for refraction work with provision of spectacles; for the ascertainment of blind, deaf, defective, or epileptic children at the school clinic; for the operative treatment of tonsils and adenoids and aural conditions by arrangement with the Stockport Hospital; and for the care of orthopædic cases, through the special department of this hospital. X ray treatment for ringworm is given at the Skin Hospital, Manchester. Dr. Rowell states that 16 routine examinations are made hourly, but perhaps this rate is only temporary and necessary because of reduction in the staff. It is scarcely possible to examine children so fast and yet do justice to the doctor and the child, whilst such speed certainly does not impress parents.

Eccles.

Doubtless the increasing work of the school medical service will demand further medical assistance for Dr. J. E. Spence, who, with the part-time services of one dentist and an ophthalmologist, carries out the duties of medical officer of health and school medical officer at Eccles. There have been few changes during the past year apart from some improvement in the hygienic conditions of a few schools. The coördination of the school and public health services is emphasised; delicate children under school age are kept under supervision at the infant welfare centre, and are frequently visited in their homes by the nurses, careful records being kept in every case so that in time a full history of each child from birth onwards will be available; infants suffering from dental and visual defects can be treated at the school clinic. The number of dirty and verminous children shows a considerable increase over last year, partly because the standard of cleanliness has been raised, but also because of the lowered health and livelihood of parents. The recent provision of an ophthalmic clinic led to an increase in the number of visual defects receiving treatment, from 80 in 1923 to 304 in 1925—a striking proof of the need for such provision for the school population. No special schools exist apart from an excellent open-air school, which has benefited many children whose records are given in the report.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED DEC. 4TH, 1926.

Notifications.—The following cases of infectious disease were notified during the week: small-pox 316 (last week 313), scarlet fever 1786, diphtheria 1251, enteric fever 44, pneumonia 1021, puerperal fever 49, puerperal pyrexia 136, cerebro-spinal fever 7, acute poliomyelitis 41, acute polio-encephalitis 4, encephalitis lethargica 38, dysentery 4, ophthalmia neonatorum 99. There was no case of cholera, plague, or typhus fever notified during the week. The number of notifications of small-pox remains practically stationary, and the county incidence the same. The total of acute poliomyelitis and polio-encephalitis, taken together, namely, 45, shows a gratifying decrease. There is one notification only from Kent (Tonbridge). The three notifications from Surrey are attributed to Frimley, Wimbledon, and Woking. Rutland has again failed to report at all.

Deaths.—In the aggregate of great towns including London there was no death from small-pox, 3 (1) from enteric fever, 18 (0) from measles, 7 (2) from scarlet fever, 18 (4) from whooping-cough, 39 (16) from diphtheria, 58 (19) from diarrhœa and enteritis under two years, and 68 (14) from influenza. The figures in parentheses are those for London itself. It is noteworthy that London, which provides for hospital isolation of measles, has no death from that disease; during the previous eight weeks there were only three deaths from measles in London as compared with 70 in the 105 great towns excluding London. The M.A.B. hospitals at present contain on the average 25 cases of measles.

DONATIONS AND BEQUESTS.—Mr. Oscar Wilkinson, of Sunnyside, Scarborough, bequeathed £1000 each to the Scarborough Hospital and Dispensary, the Scarborough Cottage Hospital, the Scarborough Charity Organisation Society, the Scarborough Convalescent Home for Children, the Hull Royal Infirmary, the Sheffield Royal Infirmary, the National Lifeboat Institution, the Cancer Hospital, Brompton, St. John's Hospital for Diseases of the Skin, Leicester-square, London, and St. Dunstan's Hostel for the Blind.

"Audi alteram partem."

SOCIAL CAPACITY IN DELINQUENCY.

To the Editor of THE LANCET.

SIR,—I have read with great interest the article by Dr. R. F. Jarrett in THE LANCET of Nov. 20th, but there are one or two points in the paper which seem to call for discussion. In the first place, the Porteus "maze" tests would hardly seem the best choice for determining the individual's apperceptive abilities. Their value lies in estimating powers of mental representation and planfulness in dealing with geometrical figures rather than with a concrete situation such as the individual is likely to meet with in ordinary daily life. To be sure, Porteus [1] himself claims considerably more than this for the test, but his statements have not been verified by other investigators. In my opinion, by far the most valuable test of this nature, and one which has a fairly high correlation with social apperceptions, is Healy's "Pictorial Completion II." [2] In this test, which is, I believe, too little known in England, the examinee is faced in pictorial form with ten concrete situations such as he is likely to meet with in everyday life, these situations varying from picture to picture instead of being, as in the Porteus "maze" tests, all the same type.

Even in this test (P.C. II.), though considerable work has been done in correlating the test results with the social efficiency of the individual, the best authorities make decidedly guarded statements. Bronner,[3] in a very thorough investigation of 1043 mentally normal individuals, of whom 729 were repeated offenders, states that "case studies show that in some instances defective apperceptions are directly related to delinquency, indeed, are, perhaps, the main cause," and that "it is worth while to study the apperceptive abilities of individuals because they represent a particularised ability that has prognostic value and important social implications." She adds, however, that "delinquents as a group, even repeated offenders, have apperceptive ability not differing from non-delinquents sufficiently to be significant." Perry,[4] in the study of 340 feebleminded individuals, concludes that "analysis of test results and social behavior in some of the irregular cases suggests that in the Healy 'pictorial completion II.' we may have a valuable tool for aid in discovering those of the feebleminded who have the mental traits most necessary for social adjustment." In view of these distinctly moderate statements, it seems that one should be very wary of accepting any test, or even a group of tests, as indicating the possible social reactions of the individual. It would be interesting to check Dr. Jarrett's results by an investigation of the after-career of the tested individuals and also to compare his findings with the results obtained from testing a group of non-delinquent individuals of similar age, educational opportunity, and social status. So far as I understand from the paper, neither of these investigations has been carried out.

Again, Dr. Jarrett quotes Burt as stating that "conduct and misconduct are always, in the last analysis, the outcome of mental life," and deduces from this that Burt considers the delinquent to be a person of peculiar "innate mental constitution." Surely no one who has read Burt's[5] careful and thorough work can fail to appreciate the very great stress which he lays on environmental conditions of every type. Were delinquency due to innate, and, therefore, irremediable causes, no treatment, whether in the form of punishment, detention, foster-home placing, or other mode of attack would be of any avail. In this connexion I should like to mention the recent and remarkable work of Healy and Bronner,[6] in which, in a thorough investigation and follow-up of the careers of 4000 delinquents, extending over a period of 14 years, the causes of delinquency and results of various methods of prevention and treatment have been assessed in an unusually scientific manner. On the basis of these investigations, they conclude that hereditary factors and so-called innate mental characteristics are of little value in prognosis and show but a very low correlation with the ultimate success or failure of their cases.

I agree with Dr. Jarrett that there is at present much loose and unscientific talk concerning the causation of delinquency, but is this an adequate reason for falling back upon the gloomy and fatalistic conception of innate and incurable defect? Recent researches have done much to disprove this doctrine and to show the very great value of constructive treatment suited to the requirements of the individual offender. What is urgently needed to-day is a scientific evaluation of *all* the factors concerned in making the delinquent what he is. This must be the first step in the development of a rational therapy which is already long overdue.—I am, Sir, yours faithfully,

R. EVELYN LUCAS,
Rockefeller Medical Fellow.

CYCLIC VOMITING.

To the Editor of THE LANCET.

SIR,—My experience of cyclic vomiting in childhood corresponds essentially with that of Dr. Cameron, but I would also direct attention again to the remarkable cases I published in THE LANCET (1924, i., 1045) of volvulus of the small intestine in which the diagnosis of cyclic vomiting had been made. I am inclined to think that there is something more to be learnt about the influence of abnormal mobility of the intestines as a factor in some of these cases of cyclic vomiting than is commonly supposed. Although the bearing of such curious and exceptional cases on the subject is obscure, the American observations commented upon in your annotation interested me as an independent contribution to the problem. One other point of interest is that I have had under my care several cases of cyclic vomiting who in earlier life had suffered from cœliac disease.

I am, Sir, yours faithfully,

F. JOHN POYNTON.

Devonshire-place, W., Dec. 11th, 1926.

THE DISSOLUTION OF INSULIN.

To the Editor of THE LANCET.

SIR,—Dr. Funk's reputation as a biochemist renders a careful consideration of any statements he may make necessary, but I agree with Dr. Lawrence that the letter published in your issue of Nov. 27th is not as clear as could be wished. Dr. Funk's second letter states his position more definitely, but does not furnish sufficient detail for a critical examination of his claims, and until this is available useful criticism is not possible.

The hyperglycæmic effect of ordinary insulin in rabbits, referred to by Dr. Lawrence, appears to have been first described by Zondek and Ucko in 1925.[1] Early this year a similar effect in several cases of diabetes was reported by H. J. John.[2] I have met with a few diabetics in whom the first effect of injected insulin has been to cause a rise in the blood-sugar, and experiments Mr. Howard and I have carried out with rabbits and guinea-pigs have shown that in certain animals an initial hyperglycæmia can be regularly induced under suitable conditions. The

[1] Klin. Wchschr., 1925, iv., 6.
[2] Jour. Lab. and Clin. Med., 1926, xi., 6.

most important factors appear to be the level of the fasting blood-sugar and the dose of insulin employed, a small dose of insulin giving rise to a more pronounced initial hyperglycæmia in healthy animals with a high fasting blood-sugar, of 120 mg. or more, than in those with a low fasting value, of 80 mg. or less; when the dose of insulin is increased the hyperglycæmia becomes less pronounced and more evanescent, so that eventually it either fails to develop, or is too quickly obliterated to be detected, this effect being more readily induced in low than in high blood-sugar animals, as we showed in a paper read before the Royal Society of Medicine this summer.[3]

As long as the exact nature of the causes determining the normal level of the blood-sugar are not decided, the interpretation of such results, and findings like those described by Drs. Funk and Lawrence, must remain largely a matter for conjecture. In the paper referred to we suggested that the occurrence of unusual fasting blood-sugar levels in apparently healthy animals and the paradoxical influence of insulin on the blood-sugar of some, might be dependent upon differences in the balance between the activities of the ductless glands regulating carbohydrate metabolism, the delayed fall and occasional initial rise following an injection being partly due to the neutralising effect known to be exerted by pituitrin upon the hypoglycæmic action of insulin.

I am, Sir, yours faithfully,
P. J. CAMMIDGE.

Nottingham-place, Marylebone, W., Dec. 4th, 1926.

AFTER-EFFECTS OF POISON GAS.

To the Editor of THE LANCET.

SIR,—The contribution to this subject made by Dr. Nelson in your issue of Dec. 11th is of interest and value to others than those who are chiefly concerned with conditions that are the aftermath of the Great War, since the after-effects of poison gas in war have some counterpart in conditions arising in industrial life. For those who are constantly seeing men who were gassed during the war Dr. Nelson's paper is particularly interesting, since the pathological findings in his case fit in so well with the clinical picture these men so often present. Anyone particularly interested in this subject will find an excellent *exposé* of it in an address by Dr. Émile Sergent delivered at Val-de-Grâce in January, 1925, which is included in his "Études Cliniques sur la Tuberculose et les Maladies de l'Appareil Respiratoire," second edition, published by Maloine, Paris, 1926. It is interesting to find that the views of Dr. Nelson and of Profs. Sergent and Achard as to the effects of *les gaz chlorés* are practically identical.

I am, Sir, yours faithfully,
Manchester, Dec. 11th, 1926. JOHN H. P. GRAHAM.

Obituary.

HENRY STOKER, F.R.C.S.I., D.P.H.

NEWS has reached this country of the death of Colonel Henry Stoker, at the Royal Military College, Duntroon, Australia. He came of an old professional family and both his father and grandfather (1773–1845) were prominent in medical practice, his father being Dr. E. A. Stoker, of Dublin. The fourth of seven brothers, all but one of whom took up medicine, Henry Stoker was educated at Bective College and Trinity College, Dublin, and qualified in 1884. Like his father and three of his brothers, he became a Fellow of the Royal College of Surgeons in Ireland. Interested in all forms of outdoor sport he will be remembered by contemporaries as a prominent member of the Wanderers Rugby Football Club, playing with his brothers, two of whom reached international standing; he himself just missed this distinction, being selected for the reserves. Dr. Stoker early decided to make his home in Australia and after taking special courses of study at continental centres was appointed sanitary officer to the port of Melbourne. During his time of office he did good pioneer work in connexion with fly-borne diseases, but his interest in surgery soon led him to give up his official appointment. Moving to Wagga Wagga he developed a large practice, and became recognised as one of the leading surgeons in New South Wales. On the outbreak of the late war he joined the Australian Army Medical Corps, and when the war was over the Federal Government marked its appreciation of his services by appointing him to the Royal Military College, Duntroon, where he remained until his death.

Colonel Stoker's wife, a daughter of the late Mr. James Poe, of Kilkenny, was killed in a carriage accident a year ago. He leaves two sons.

EDMUND JOHN ERSKINE RISK, M.R.C.S. ENG.

Colonel E. J. Risk, who died in London on Dec. 7th at the age of 68, was a son of the late Rev. John Erskine Risk. As a student at St. Bartholomew's Hospital he distinguished himself both in scholarship and athletics. He qualified M.R.C.S. Eng., L.R.C.P. & L.M. Edin. in 1880, and in the following year entered the Army Medical Service, proceeding to Malta. He served in the Egyptian campaign and was present at the battle of Tel-el-Kebir. After living for some time in India he was, in 1891, invalided home suffering from dysentery and malaria. After 12 months' sick leave he was posted to the Aldershot Command, and three years later went to the West Indies, where he served nearly six years at Barbados and St. Lucia. In 1901 he was on the embarkation staff at Southampton, and in December of that year sailed for South Africa on the hospital ship *Simla*, of which he took medical charge at Lorenzo Marques for three months. Next he proceeded to Elandsfontein, where he had charge of the surgical division, and after a further period of service at home and in Ireland he returned to South Africa, and was appointed senior medical officer at Bultfontein, Orange River Colony, a post which he held until 1910. Appointment to the Irish Northern Command followed, and in 1911 he became Commandant and Director of Studies at the Royal Army Medical College, Milbank. Unfortunately his health failed, and he had to retire in 1913.

Colonel Risk leaves a widow and one daughter.

LONDON STREET ACCIDENTS.—The London County Council has decided to ask the Ministry of Transport to call a conference to consider street accidents in London. In the three months, July–September, there were 269 fatal accidents, a large increase over former figures. In the same period 26,727 persons were injured in the streets, an average of 293 per day.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH.—On Nov. 23rd Prof. Adam Patrick read a paper on Diabetic Coma. After referring to the facts known about the chemistry of ketosis, he showed how imperfect carbohydrate utilisation may be the result either of deprivation of sugar or inability to assimilate it. He emphasised the importance of aceto-acetic acid in the body and pointed out that there was no object in elaborating tests to distinguish this substance from acetone in the urine. Dealing with the symptomatology of coma, Prof. Patrick laid stress on the early signs, especially abdominal pain. He advised treating every symptom which appeared out of the ordinary as the possible commencement of coma. Contrasting the symptoms of coma with those of hypoglycæmia, he showed how in the latter the prominent symptoms are nervousness, mental excitement, tachycardia, and perhaps diplopia. Dealing next with treatment, he referred to the importance of making every effort to prevent the occurrence of coma by attention to the diet laid down, and especially by avoidance of any change which will cause difficulty in accurately adhering to the ordered regimen. In conclusion, he gave a detailed account of methods of treatment of coma once established, up to 200 units of insulin being given in the 24 hours with control by two-hourly examination of specimens of urine. He mentioned the utility of the duodenal tube in facilitating the introduction of large quantities of fluid, as recommended by Poulton.

[3] Proc. Roy. Soc Med., Sect. of Med., 1926, xix., 37.

THE SOCIETY OF APOTHECARIES.

PRESENTATION TO PROF. W. E. DIXON.

THE Master and Wardens of the Society of Apothecaries of London gave a dinner on Tuesday last, Dec. 14th, at their Hall, the occasion being the presentation to Prof. W. E. Dixon of the Society's Gold Medal for Therapeutics. The presentation was made by the Master, Dr. Alfred Hepburn, who outlined the development of the medical profession since the times when it was divided into the physicians who possessed university degrees and very generally extended their knowledge by continental travel; the apothecaries who possessed a definite status in therapeutics; and the surgeons, whose Company was allied to the Company of Barbers, and who were mainly engaged in blood-letting. He sketched the rise of the Royal College of Physicians of London from the days when election to that body was in the hands of the Bishop of London, the Dean of St. Paul's, and four medical Censors; and, admitting that there had been times when the College and the Society of Apothecaries were at variance, pointed out that harmony now prevailed in the common desire to promote therapeutics. In this connexion he gave reasons for finding Prof. Dixon a highly fitting recipient of the Society's Gold Medal.

Prof. Dixon, in acknowledging a deep sense of the compliment, pointed out that the trend of modern thought was showing the human body itself to be an apothecary's shop, doling out remedies as required from its own physiological resources, which were thus shown to be distinctly therapeutic. In the matter of surgery, he alluded to the vast opportunities for surgical progress that were opened up by the chemical and pharmacological work which resulted in the discovery of anæsthetics.

Dr. R. W. Statham, the Senior Warden, proposed the toasts of the Royal Colleges which he coupled with the names of Sir John Rose Bradford and Sir D'Arcy Power. Sir John Rose Bradford, while agreeing with the emphasis that had been laid by previous speakers on the essential value of treatment, pleaded that there was still room for the physician, inasmuch as it was generally admitted that diagnosis should come first, while diagnosis was largely dependent upon a knowledge of pathology. Sir D'Arcy Power, in a learned excursion into the history of medicine, pointed out that the apothecaries had developed from a Guild of Pepperers, and had early secured freedom, while the independent Company of Surgeons fell into bondage to the Barbers, emergence from which meant bankruptcy at the time the separation was made.

The toast of The Guests was proposed by the Junior Warden, Lieut.-Colonel C. T. Samman, and was replied to by Mr. Arthur Denman, who interested the company with a narration of his medical ancestry. His great-grandfather, he said, was Thomas Denman, the famous accoucheur at the close of the eighteenth century, whose three children were—one son, who became Lord Chief Justice of England, and two daughters, of whom one married Dr. Matthew Baillie, the pioneer in clinical pathology, who presented "the gold-headed cane" to the College of Physicians, and the other married Sir Richard Croft, the well-known obstetrician, who had the misfortune to attend the Princess Charlotte, the only daughter of George IV., in her fatal confinement. Through his great-grandmother, he said, Sir Benjamin Brodie and Prof. Brodie also came into the pedigree.

The speeches were interspersed with a programme of music provided by Miss Olive Kavann and Mr. Percy Kahn.

GUY'S HOSPITAL.—The Matron, Miss Margaret Hogg, C.B.E., is to retire from the service of the hospital on March 27th, and Miss Emily MacManus, Matron of the Bristol Royal Infirmary, has been appointed to take her place.

The Services.

ROYAL NAVAL VOLUNTEER RESERVE.

Prob. Surg. Sub-Lt. T. A. Brand is confirmed in his rank.

ROYAL ARMY MEDICAL CORPS.

Capts. to be Majs.: E. L. F. Nash, M. Morris, W. E. Adam, R. H. Lucas, M. P. Power, G. B. Hadden (Prov.), and F. J. Hallinan.

Temp. Capts. to be Temp. Majs.: W. Duguid, H. L. Mann, J. Boyd, J. L. Dimond, H. Davies-Colley, St. G. E. Harris, E. K. Campbell, F. C. Doble, and W. B. Swete-Evans.

ARMY RESERVE OF OFFICERS.

Lt.-Col. H. G. P. Stallard having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

ARMY DENTAL CORPS.

Capt. S. J. F. Webb, late Dental Surg., Gen. List, to be Capt.

TERRITORIAL ARMY.

Lt.-Col. L. D. Bailey to be Bt. Col.

Capt. G. P. Crowden (late K.O.Y.L.I.) to be Lt. super. for service with the Medical Unit of the London University O.T.C., and relinquishes the rank of Capt.

Capt. R. I. Dacre to be Maj.

Lt. W. B. McCall to be Capt.

ROYAL AIR FORCE.

R. A. W. Kerr and E. Thompson are granted short service commissions as Flying Officers for three years on the active list.

G. E. Church is granted a short service commission as a Flying Officer for three years on the active list, and is seconded for duty with the Royal Albert Edward Infirmary and Dispensary, Wigan.

Flying Officer B. W. Cross is promoted to the rank of Flight Lt.

INDIAN MEDICAL SERVICE.

The King has approved the retirement of Lt.-Col. E. F. G. Tucker.

Capts. R. Hay, M. Murphy, Jehangir Hormusji Oonvala, H. E. Murray, and W. H. Will to be Majs.

The King has approved the grant of a temporary commission to Tharuvi-parambil Reghunatha Pai Rama Pai.

The King has approved the relinquishment of their temporary commissions by Capts. Shivax Ardeshir Paymaster (permitted to retain the rank of Capt.), Showkiram Sahijram Malkani (permitted to retain the rank of Capt.), and Jehangir Cursetji Bharucha.

Dr. Ganga Charan Garg, Provincial Medical Service, medical officer, District Jail, Lucknow, to be Medical Officer in immediate charge of the Sadr Dispensary, Rai Bareilly. Dr. Bhagwati Prasad Mital, medical officer of health on special duty plague research work, to revert as Medical Officer of Health, II. Class. Lt.-Col. C. C. Cumming to be officiating A.D.M.S. Allahabad Independent Brigade Area. Capt. H. R. Cursetji to be Specialist in Ophthalmology, Rawalpindi District. Capt. R. McRobert to be Officiating Specialist in Surgery, Burma District. Capt. P. M. Antia to be Deputy Assistant Director of Pathology, Bombay District, and Capt. A. Y. Dabholkar to be Officer-in-Charge, Brigade Laboratory, Bareilly. Lt.-Col. W. L. Harnett, superintendent, Campbell Medical School and Hospital, is nominated to be a member of the Bengal Council of Medical Registration, vice Lt.-Col. M. Mackelvie. Dr. E. Muir, pathologist and research worker in the School of Tropical Medicine, Calcutta, to be a Member of the Governing Body of the State Medical Faculty for a period of two years, vice Maj. Hasan Suhradardy. Dr. Kedarnath Das to the Bengal Council of Medical Registration, in place of Dr. Pramatha Nath Nandi.

HEALTH CENTRE IN NEW YORK.—On Nov. 28th a health demonstration centre was opened in East 38th Street. The building in which it is housed has been altered and equipped by the Milbank Memorial Fund, and contains model clinic and consultation rooms, a rest room, a large roof for patients, and a lobby where information about health is freely given. The centre is in one of the most congested parts of New York. An account of the work of the Milbank Trust appeared in THE LANCET of Nov. 13th (p. 1023).

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

THE CORONERS (AMENDMENT) BILL.

THE Coroners (Amendment) Bill was considered by Standing Committee D of the House of Commons on Tuesday, Dec. 7th. Mr. MORGAN JONES was in the chair.

On Clause 1 (which deals with the qualifications and disqualifications of persons for appointment to the office of coroner),

Mr. RHYS DAVIES moved an amendment to provide that a dual qualification, legal and medical, should be required for appointment as coroner. He said that he understood that the dual qualification had appertained in London for some years, and he did not believe that there had been any difficulty in filling the posts in consequence. He thought that what was good enough for London ought to be good enough for large centres like Manchester, Leeds, Glasgow, and Liverpool.

Captain HACKING (Under Secretary for the Home Department) said that the number of coroners in London was small compared with the number of coroners throughout the country. There were about 300 coroners throughout the country, and it would restrict the choice very much if they insisted upon a dual qualification.

The amendment was negatived.

On Clause 5 (salaries of county and borough coroners),

Captain HACKING moved a new subsection (4) as follows: "The salary payable under this section of a borough coroner shall be instead of the fees and allowances specified in the Fourth Schedule to the Municipal Corporations Act, 1882, and the additional payment mentioned in Subsection (2) of Section 27 of the Coroners Act, 1887, or the remuneration payable under any Act, or Provisional Order confirmed by an Act, as the case may be, and no such fees, allowances, additional payment, or remuneration as aforesaid shall be payable to a borough coroner after the commencement of this Act."

The amendment was agreed to.

Captain HACKING moved to insert at the end of Subsection 5 the words: "The salary of a borough coroner shall in default of agreement between him and the council by whom his salary is payable be at a rate fixed by the Secretary of State."

The amendment was agreed to.

On Clause 11 (appointment of assistant deputy coroner),

Mr. GATES moved an amendment to include franchise coroners.

Captain HACKING, in resisting the amendment, said that under the Bill franchise coroners would cease to exist. The existing power of a county or borough coroner to appoint a deputy rested upon Statute, but it was not so with franchise coroners. Any power that they had to appoint a deputy rested upon prescription and custom. There was no object in bringing franchise coroners within the provisions of the Bill.

Mr. GATES said it was true that franchise coroners were destined to perish ultimately, but as long as they existed they should have the power to carry on their courts. If the coroner was ill and his deputy was ill, there was nobody to carry on the work, and inquests might be delayed.

Captain HACKING said that there had never been any difficulty to his knowledge, and no fear need be entertained that inquests would be delayed.

The amendment was negatived.

On Clause 14 (view of the body and burial order),

Captain HACKING moved to leave out Subsection (2) and to insert a new subsection as follows:—

"Subject to the provision of any rules made under this Act an order of a coroner authorising the burial of a body upon which he has decided to hold an inquest may be issued at any time after he has viewed the body."

He explained that the subsection in the Bill was a re-enactment of a provision in the Coroners Act, 1887, with certain modifications. The Births and Deaths Registration Bill, which was at present going through Parliament, affected this matter, and until that Bill was placed on the Statute Book it was impossible to know exactly what it would contain. This clause, however, must work in connexion with that Bill, and it was thought more desirable that the Lord Chancellor should have the opportunity of issuing Regulations and Rules rather than lay down something in the Bill which might prove unworkable.

The amendment was agreed to.

On Clause 17 (inquests where several deaths arise from one accident),

Mr. LEE moved an amendment to provide that the coroner in the district in which the accident occurred should conduct the inquiry.

Captain HACKING said there were many cases where it was advantageous that the inquest should not necessarily be held at the place where the accident happened. Several people might be badly injured in a colliery accident, and might be taken to the nearest town where there was a hospital, and if they died there it would not be advisable to remove the bodies to another district in order to hold the inquest. It might be for the convenience of everyone that the inquest should be held at the place where the bodies were.

The amendment was negatived.

On Clause 21 (post-mortem examination without inquest),

Major-General Sir R. LUCE moved to leave out the words in Subsection (1): "post-mortem examination may prove an inquest to be unnecessary," and to insert instead the words:—

"An inquest may be rendered unnecessary by a report to him from a duly qualified medical practitioner recently in attendance on the deceased, he may direct such a medical practitioner to furnish a report, or if he is of opinion that an inquest may be rendered unnecessary by a post-mortem examination."

He said that the object of the amendment was to reduce the number of unnecessary inquests. The clause as it stood allowed a coroner to order a post-mortem in certain cases, and on the result of that examination to decide whether he should hold an inquest or not. The amendment would provide that in cases where a post-mortem was not necessary the coroner should have the power to call for a report from the doctor who had been attending the patient before death, and as a result an inquest might be unnecessary. This was not a new principle. A considerable amount of evidence was brought before the Departmental Committee in 1909, and the principle already existed in Scotland. The principle was also in operation in a particular coronership in Durham, and though it had been in practice for 30 years, it had never been challenged in the Law Courts. The coroner of Durham stated that by this method he had been able to reduce the number of inquests by 50 per cent. From his own personal experience he (Sir R. Luce) could say that a large proportion of inquests had been unnecessary and could easily have been dispensed with.

Mr. RHYS DAVIES said he was quite in favour of the proposal to reduce the number of unnecessary inquests, but were they not, if they passed this amendment, practically transferring the work of the coroner to the medical practitioner? He agreed that the certificate of the medical practitioner would be very important in most cases, but there were cases in which medical practitioners themselves were involved in certain practices which were undesirable.

Lieut.-Colonel FREMANTLE said that the amendment would regularise a practice which had existed to a certain extent. He received a letter on the previous day from a medical practitioner of great experience in a typical area covering the whole county. He wrote:—

"We frequently view the body, and if everything appears to warrant the view that death was due to natural causes, especially if the doctor has previous knowledge of the deceased, we give a written report to the coroner stating our opinion as to the cause of death. This suffices, does away with the expenses of an inquest, and the doctor gets no fee for his trouble."

The amendment would put this on a regular footing, and enable the coroner to demand such a report.

Captain HACKING said this was a very interesting subject, and there was a great deal to be said for the arguments put forward in support of the amendment. Mr. Rhys Davies had said that this would mean that the medical practitioner would be responsible for the inquest, but that was not the case. The coroner must accept full responsibility; he merely got advice from the medical officer. But the question of cost entered into the matter. This amendment, with the two consequential amendments, provided that the doctor should be paid half a guinea for his report. If this meant a necessary report in writing, it was at present open to the local authority to provide for any reasonable and necessary expenditure involved. As a matter of fact the Durham County Council, under the Schedule of Disbursements of the 1887 Act, allowed a fee of 10*s.* 6*d.* for a report. There appeared to be no reason to suppose that that was illegal, and he suggested that the medical profession, instead of asking for legislation on a matter of this kind, should move to get other local authorities who did not have this power to provide in schedules for such a fee, and if the doctors were successful in that way, as he had no doubt they would be, then the backward authorities could be brought into line by approaching the Secretary of State under Clause 29 (Subsection (2) (*b*)) to prescribe an appropriate fee for this work.

After further discussion,

Sir R. LUCE said the class of case dealt with here had developed from custom. A patient had been under a doctor for a considerable time. Perhaps he was not acutely ill, and he was not seen by the doctor for a few weeks. He might be known to be suffering from heart disease. The patient died suddenly without having seen the doctor for a few weeks or a month or two. It was extremely common for the coroner to refuse to accept an ordinary death certificate from the doctor, and an inquest was held. The doctor,

however, knew all about the patient, and could perfectly well give the coroner full information if he was properly asked to do so in writing, and in that way he could entirely avoid the necessity for an inquest.

The amendment was negatived by 21 votes to 7.

On Clause 22 (power of coroner to request specially qualified persons to make post-mortem and special examinations),

Mr. LEE moved an amendment requiring a coroner to give notice of his intention to hold a post-mortem or special examination to the trade-union representative of the deceased, and providing that such trade-union should have the right to be represented by a medical practitioner at the examination. He said that rightly or wrongly there was a prevailing idea among the families of men who died as the result of accidents that the medical man appointed by the coroner was in some way hostile to their interests, and he moved this amendment in order to secure the fullest opportunity for the family to know that complete justice had been done to their case.

Lieut.-Colonel FREMANTLE said he was in sympathy with the ostensible object of this proposal. The medical profession were only too glad to have any other medical evidence brought in to reassure suspicious minds among the lay public that the medical men had done their best and had been accurate. He thought the family ought to be represented, but he did not understand why a special privilege should be given to the trade-union representative. The matter should be left to the family, and they could, if they so desired, notify a trade-union representative under the ordinary law.

Sir R. LUCE said that although he had great sympathy with the principle of the amendment, there were considerable difficulties in the matter. In cases where the interests of the trade-union and those of the employers clashed, that would introduce the difficulty of having to consider also the rights of the employer. Most of these places were not very suitable for having a crowd to watch the post-mortem.

Captain HACKING said that he thought that it was wrong that this onus should be placed on the coroner. If the relatives cared to be represented or desired to leave the matter in the hands of the trade-union, in all likelihood the coroner would not object. There appeared to be no necessity for putting this into the Bill and making it a hard-and-fast rule. The Home Secretary had powers through the Lord Chancellor to make rules in connexion with a matter of this kind, but in all probability it would not be necessary to take action. There were occasions when a post-mortem must be carried out immediately, and it might be a very serious thing to take away the right of a coroner to order a post-mortem immediately in the interests of justice.

The amendment was negatived by 16 votes to 10.

Mr. LEE moved a further amendment to empower a trade-union in a case where the question of workmen's compensation was likely to arise, to call the medical practitioner who had attended the post-mortem or special examination on their behalf at the inquest, and ask him questions, and he should have a right to answer such questions and give evidence on any matters arising out of the examination.

Captain HACKING said that if a doctor had actually attended the post-mortem and the coroner knew he was in court, surely it would be a most extraordinary thing if he was not called to give evidence. If a coroner did not carry out his duties in such an obvious respect, the Home Secretary would certainly have something to say on the matter, and would cause an inquiry to be made.

The amendment was negatived by 16 votes to 10.

The Bill was further considered in Standing Committee on Wednesday, Dec. 8th. Mr. MORGAN JONES was in the chair.

On the further consideration of Clause 22,

Mr. SMITHERS moved an amendment that in cases where the coroner was informed by some person that in his belief the death of the deceased was caused partly or entirely by the improper or negligent treatment of a medical practitioner, or other person, that information need not be given on oath, but that the coroner could take action to prevent such medical practitioner or other person performing or assisting at any post-mortem or special examination made for the purposes of the inquest on information received.

Captain HACKING said that if it were placed at the discretion of a coroner to say that a certain doctor should be prohibited from performing a post-mortem, it would be casting a very obvious slur on certain members of the medical profession, probably without any cause and before even an inquiry had been made. The Bill as drafted afforded a much better mode of procedure.

The amendment was withdrawn.

Sir R. LUCE moved an amendment providing that a medical practitioner or other person should have the right, if he so desired, to be present or be represented at a post-mortem or special examination in a case where it was alleged that the death of the deceased was caused by the improper or negligent treatment of such medical practitioner or other person. The object of the amendment, he said, was to strengthen the position of the medical practitioner in these cases, especially if it was possible that a person might make an accusation on oath in the court after the proceedings had begun. He had known of no cases in which a coroner had refused to allow a medical man to be represented, but in view of the very definite ruling in the Act as it stood that the medical man should not direct or assist in the post-mortem examination, it seemed right that he should have his position guarded in the way he had suggested. He realised that this provision was put into the old Act because it was possible that a medical man who was quite unscrupulous might spoil the post-mortem examination. In fact, he believed it was put in on account of a very definite case in which a medical man was suspected of murder by poison. He actually jogged the elbow of the man who was performing the post-mortem examination and upset the contents of the stomach so that they could not be examined afterwards. One realised that a medical man in such circumstances should have no direct part in the post-mortem examination, but since he was debarred from that, it seemed right that he and other people concerned should have the right to be represented at the post-mortem examination.

Mr. RHYS DAVIES supported the amendment.

Captain HACKING suggested that Sir R. Luce should withdraw his amendment, and that they should adopt a form of words providing that "such medical practitioner or other person shall have the right, if he so desires, to be represented at any such post-mortem examination." He thought they might cut out the special examination.

Sir R. LUCE said he thought he could agree to that proposal. He agreed that it was impossible to have representation on all occasions at special examinations which might last for days or weeks. He thought that the post-mortem would cover the ground.

Lieut.-Colonel FREMANTLE said he thought that the legal justice of the case applied as much to the special as to the post-mortem examination. There was also the possibility that the accusation might be false, and the practitioner, by being present, might help to elucidate the facts in the interests of right and justice.

Captain HACKING said that he thought that he had met the Committee very fairly in offering this concession. He thought that they might leave the question of the special examination to the discretion of the coroner.

After further discussion Sir R. LUCE withdrew his amendment, and the form of words suggested by Captain HACKING was agreed to.

On Clause 23 (fees to medical witnesses),

Sir R. LUCE moved an amendment to secure that the medical practitioners should be paid for each day's attendance to give evidence. At the present time, he said, the rule was that, however many days or however many times the court might adjourn, the doctor could only be paid a fee for one day, although he might have to attend the court two or three times. That procedure existed in no other court in the country, and he thought it ought to be abolished.

Captain HACKING said in substance he was quite prepared to accept this amendment, but if the hon. and gallant Member would withdraw it, he would move another form of words to provide that medical witnesses should receive one and a half guineas for each day on which they were required to attend.

Sir R. LUCE accepted Captain Hacking's offer.

Captain HACKING then moved the substituted form of words which he had suggested.

After some discussion, Captain HACKING'S amendment was agreed to by 18 votes to 2.

Captain HACKING moved an amendment to provide that the fee for a post-mortem examination should be two guineas, instead of one and a half guineas as provided in the Bill.

Mr. RHYS DAVIES said he wanted to know how it came about that Captain Hacking had succumbed so early to his hon. friends in connexion with these fees. What was fair for the doctors in the opinion of the Home Office when the Bill was drafted must be fair now. At the same time, he wished the Bill to pass.

Sir R. LUCE moved that the fee should be three guineas. He said that the Committee would realise that a post-mortem was not a pleasant job. It was a job of great importance and of considerable danger to the medical practitioner. Compared with other operations of the same kind requiring considerable skill it had hitherto been paid for disgracefully, and he was glad that the Home Office had agreed to some increase. But he did not think that the increase from one to two guineas was sufficient for the severe work that had to be done at a post-mortem.

The amendment to increase the fee to two guineas was agreed to.

Sir R. LUCE moved an amendment to provide that medical practitioners who made a post-mortem examination of the body of a deceased person (including a report, if any, of the result thereof to the coroner), and attended to give evidence at an inquest on the body, should receive four guineas for the first day of attendance and one and a half guineas for each subsequent day, instead of two guineas, as stated in the Bill. He said he understood that the Under Secretary was prepared to agree to three guineas in this case, and he thought they had better accept that proposal.

Sir R. LUCE withdrew his amendment, and Captain HACKING moved an amendment giving three guineas and one and a half guineas respectively.

Mr. RHYS DAVIES said he entered his protest against the way in which this clause had been amended. They were not opposed to proper payment to doctors, but he did not like the way in which this had been done. He was not so sure that had the medical practitioners been on the Labour side and not on the Conservative side the Under Secretary would have acceded so readily to their claims.

Captain HACKING pointed out that there were doctors who were members of political parties other than the Conservative party, and these fees were to be given to doctors generally. The Home Office considered that the present fees were too small for the work that was performed.

Captain HACKING's amendment fixing the fees at three guineas for the first day and one and a half guineas for each subsequent day was agreed to by 14 votes to 6.

The Committee stage was concluded, and the Bill was ordered to be reported to the House.

Mental Deficiency Bill Dropped.

The Government have found it impossible, owing to the pressure of Parliamentary business at the end of the session, to make further progress with the Mental Deficiency Bill, and the measure has accordingly been dropped for this year.

HOUSE OF LORDS.

WEDNESDAY, DEC. 8TH.

MILK AND DAIRIES ORDER.

Lord STRACHIE moved: "That an humble address be presented to His Majesty praying that the Milk and Dairies Order, 1926, dated 6th July, 1926, be annulled." He said that he was not objecting to the Order *en bloc*, quite the contrary. He thought that many of the 33 articles were most excellent, necessary, and desirable. He was taking serious objection only to three. They would all agree as to the necessity for the utmost cleanliness to be observed by the milkers, that the cows should be kept clean and their udders free from dirt before they were milked, and also that the milk churns should be thoroughly and properly cleansed before use after being sent back. The American view was that 80 per cent. of the impurities in milk could be attributed to the handling of the milk. But what he objected to was the enormous expense which was put on owners large and small by certain provisions of this Order. He could not understand why Articles 27 and 29 of the Order, which provided for the keeping of milk churns and receptacles in proper order, should not come into force for one year and nine months. He could not help thinking that in this case the manufacturers had had a great deal more influence with the Ministry of Health than the agriculturists had. Surely it was most important that these churns should have a proper lid and that nothing of a contaminating nature should enter into them during transport. Article 8 provided that every county council and county borough should cause to be made such inspection of cattle as might be necessary and proper for the purposes of the Act and the Order. Why should it be necessary, Lord Strachie asked, for every county council and county borough to make an inspection of the whole of the cattle in their area? He thought that the onus should remain as it was now, on the owners of the cattle, to report to the local authority if and when they knew that any of their cattle were diseased. If the owners did not report any disease in their herd, then by all means let them be prosecuted. The noble lord also objected to Articles 12, 13, and 25 of the Order on the ground that they prescribed structural conditions in connexion with dairies and cowsheds which, he said, would impose enormous expense on owners and owner-occupiers of dairy farms. This was not a time when such expenditure could be afforded. He noted that Mr. Chamberlain had promised to send out a Circular to local authorities emphasising the need of the reasonable administration of the Order, having regard to the difficulties attaching to milk production, but even if such a Circular were sent out, there was no certainty that the local authorities would pay attention to it.

After some discussion,

Lord BLEDISLOE (Parliamentary Secretary to the Ministry of Agriculture) said that with some little knowledge of the conditions prevailing in most other civilised countries, he asserted that such a debate could not have taken place in a legislative chamber in any other civilised country of the world. In these matters most civilised countries were unfortunately very far ahead of us, because they had paid greater attention to the fact that the health of the community was undoubtedly affected injuriously by the consumption or ingestion of polluted milk, and had taken more drastic action in consequence. The consumption per capita of milk in this country was disgracefully small—in fact, smaller, as far as they knew, than in any other highly civilised country in the world; and all health authorities, as far as he knew, were prepared to admit that the health of the nation, and particularly of its children, was suffering in consequence of the inadequate consumption of milk. Noble lords might say that that did not affect the question under discussion, but he thought it affected it very materially, because if there was an opinion abroad—as there had been an opinion abroad, which had been exaggerated by enthusiasts and extremists in this matter—that there was what was sometimes called "poison in the milk pail," it acted as a serious deterrent to the consumption of milk among the poorer population, who sought to find some alternative, when there was no alternative, so far as the infantile population was concerned, to milk as a food. They were told on the best authority that the reason why farmers had not been able to make a sufficiently good milk contract was that there existed a surplus of milk at the present time in this country; or, in other words, there was an insufficient demand on the part of the population generally for the available supply. Was it not fair to assume that to some extent this was due to the fact that the milk supply was not all that the most enlightened people would like to see it in this country? Medical officers of health in certain cities to his knowledge had given public advice against the consumption of liquid milk by infants in their administrative areas, and had gone so far as to advocate in preference the consumption of milk powder or dried milk coming from foreign countries. That was not good for the dairy farmer or the dairying industry, and if they made some reasonable concession to enlightened public opinion on medical grounds it was more than possible that the demand for milk would increase and the dairy farmer in consequence would be more prosperous. The Ministry of Agriculture held the view to-day, based upon the reasons which he had submitted to their lordships, that it was not in the best interests of the farmers themselves to stand in the way of reasonable improvement of the methods of milking cattle and handling milk. For that reason they had been in quite amicable conference with the Ministry of Health in arriving at the final form of this Milk and Dairies Order.

On a division the motion to annul the Order was defeated by 63 votes to 21.

EXPERIMENTS ON STOLEN DOGS.

Lord BANBURY asked the Government whether their attention had been drawn to the case at Clerkenwell Police-court on Dec. 1st, where a man was charged with stealing a dog which he had sold to the University College School of Physiology; whether they were aware that a man was convicted at Bow-street on Nov. 20th for receiving two stolen dogs which he was taking to the University College School, and what steps they intended to take to stop this practice. The noble lord quoted an explanation issued by the College authorities after certain remarks had been made by Mr. Fry, the magistrate in the Bow-street case. In the course of the explanation it was stated that the professor of physiology had always taken special precautions to prevent the delivery of stolen dogs in that he required a written guarantee that all the animals so delivered by the man Hewett (who had been convicted at Bow-street of feloniously receiving two Irish terriers valued at £7 and of cruelly ill-treating the dogs) and the other dealer with whom the professor traded were legitimately obtained. Commenting on this, Lord Banbury said that no one, unless he was of opinion that in all probability the article had been stolen, would ask for a written guarantee that the article had been legitimately obtained. The dogs, which were stated to be of the value of £7 each, were bought by the School for 6*s*. each. If a diamond ring worth £50 was offered for a couple of sovereigns, one generally had some suspicion that something was wrong. Apparently this gentleman had no suspicion of that sort. The College explanation also stated "that the dogs found in the possession of Hewett at the time of his arrest were, so far as is known, not of the type required by the College; they were never offered to, and were consequently not seen by, anyone at the College." They were not seen by anyone at the College, Lord Banbury continued, because the detective had stopped the man at the door of the College. It was proved in evidence that he was going to take them to the College, and that he would have received 6*s*. each for them. In the report of the Clerkenwell Police-court case it was stated that "a boy of 14, who said he was 'animal attendant' at University College, said he had known the defendant for about four

weeks. He helped a man named Jackson to fetch dogs to the College." Lord Banbury said that it was curious that a boy of 14 should be employed to look after animals. When he brought in his Bill in the House of Commons to prevent dogs being vivisected, Dr. Chapple, then a member of the House of Commons, gave as a reason against the Bill that dogs were cheap. It would cost, he added, £5 to get a suitable monkey. It was evident, therefore, said Lord Banbury, that one of the reasons why it was necessary to have dogs for this purpose was because they could be obtained cheaply; and now they knew how it was that they were obtained. Dr. Swan, in giving evidence before the Royal Commission, was asked: "In addition to that, is it not the case that dogs are more expensive than other animals, so that the very lowest motive, the motive of pocket alone, would cause them to prefer other animals?" Let their lordships mark his answer: "You can steal a dog anywhere." Dr. Swan was then asked: "You do not mean to imply, do you, that the dogs used in physiological laboratories are stolen and not paid for?" He replied: "I have stolen dogs in my early days." Continuing, Lord Banbury said he thought it was clear that the habit of receiving stolen dogs was somewhat prevalent at these institutions. It was a matter which was very difficult to trace, but two cases had been brought to light in the last fortnight. He urged that something should be done to prevent this practice.

Earl RUSSELL said that he was not an anti-vivisectionist, but he suggested that stray dogs should be taken for this purpose that otherwise would be destroyed. That, he understood, was forbidden by law at present, but he would be glad to see that law repealed. If it could not be repealed, he suggested that it might be provided by Statute that dogs should not be used by physiological laboratories unless they had been bred by the laboratories themselves. One breeding establishment might be set up to supply several laboratories, and they might then be prohibited from using any dog of which they could not trace the history from birth. That would prevent this particular evil. Speaking not only for himself but for all lovers of dogs, he believed the public conscience had been roused by what had happened and was entirely in sympathy with the remarks both of Mr. Fry (the magistrate) and of Lord Banbury, and it would not rest until something had been done to make it impossible in the future.

Lord DESBOROUGH, replying for the Home Office, said that he did not believe for a moment that University College encouraged the stealing of dogs. The College authorities bought dogs for physiological purposes—he could not go into the matter as to whether it was a wise thing to do or not—from recognised dealers, and not only that, but they said that they asked for a written guarantee that the dog had been honestly come by. The College had no reason to believe that Hewett was not an honest dealer in dogs. He (Lord Desborough) fully joined in the sympathy which had been aroused in this case, and he would take any strong measures he could if he thought that his own dogs were going to be stolen and experimented upon. But these two instances did not make out a very strong case for the suggestion that this was a very prevalent thing, and the imputation that University College encouraged it seemed to him to be absolutely unfounded. He thought they had taken every precaution they possibly could. With regard to Earl Russell's suggestion he was told that every year in London 25,000 dogs were destroyed. He fully agreed with Earl Russell that those were the dogs which should be used for this purpose, always admitting that dogs should be so used, and he had defended that in the House before. He had no right on this new suggestion to speak for the Home Office, but as far as he knew they did not think it was a very wise provision in the Act of 1906, which absolutely prevented dogs that were going to be destroyed from being used for a useful purpose before they were painlessly destroyed. He did not know whether Earl Russell saw the other day that in destroying dogs they were burned and subsequently poisoned.

Earl RUSSELL: Subsequently poisoned?

Lord DESBOROUGH said he read in a newspaper that an accident happened to the asphyxiating chamber, the top was blown off, and the dogs were injured and subsequently poisoned. He would no more make an accusation against the Battersea Dogs' Home on that account than he would against the London School of Physiology that they were in the habit of buying stolen dogs or wishing people to steal dogs. He did not know what Lord Banbury wanted. They could not alter the law relating to vivisection that night, and he had not made any suggestion. But as to the suggestion of Earl Russell, he personally thought—and he believed the Home Office would agree—that it was a most excellent one, and he hoped something might be done in that direction.

Lord BANBURY said he would suggest that the Home Office should give instructions to the police to investigate the approaches to these different schools extremely carefully, and to prosecute in any case in which they found that a dog had been stolen, or had been received knowing that it had been stolen.

THURSDAY, DEC. 9TH.

Births and Deaths Registration Bill.

The Births and Deaths Registration Bill passed through Committee.

MONDAY, DEC. 13TH.

The Births and Deaths Registration Bill was read the third time and passed.

TUESDAY, DEC. 14TH.

The Coroners (Amendment) Bill.

The Lord CHANCELLOR moved that the Commons' amendments to the Coroners (Amendment) Bill should be agreed to. He said that he had gone through them very carefully, and he advised their lordships to agree with all the amendments.—The amendments were agreed to.

HOUSE OF COMMONS.

WEDNESDAY, DEC. 8TH.

University of London Bill.

The University of London Bill, as amended in Standing Committee, was considered on Report and read a third time.

Infantile Paralysis.

Mr. REMER asked the Minister of Health if his attention had been called to the outbreak of infantile paralysis in this country; if he was aware that in the United States of America, where the outbreak had been more serious, medical research had revealed that this complaint was caused by the exposure of uncooked foods to contamination with germs contained in dust, and that consequently a law had been passed providing in that country all such foods must be covered; if his Ministry had made any inquiries into this matter; and if he was prepared to make any statement.—Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) replied: The answer to the first part is in the affirmative. As regards the second part, my right hon. friend understands that, although it was claimed in America that the virus if this disease had been found in the dust of sick rooms, this claim has not been confirmed, and he is advised that there is no direct evidence that the virus is in fact transmitted by uncooked food, and there is no reason to think that this means of transmission of the disease is an important factor in the present prevalence.

Mental Deficients and Marriage.

Sir ROBERT GOWER asked the Minister of Health whether he would consider the desirability of introducing legislation making it a punishable offence to marry, or connive in the marriage of, any person known to be certified as a mental defective under the Mental Deficiency Acts.—Mr. NEVILLE CHAMBERLAIN replied: My hon. friend's suggestion is certainly worthy of consideration, but I doubt whether there is a sufficient measure of agreement as to facts or conclusions to justify the introduction of legislation at present.

Deaths from Lead Poisoning in the Pottery Trade.

Mr. SHORT asked the Home Secretary the total number of deaths due to lead poisoning in the pottery trade during 1925; the average age of the deceased; and whether an improvement was shown on 1924.—Captain HACKING (Under Secretary for Home Affairs) replied: The total number of deaths in 1925 was 5, and the average age 58. These figures are better than the corresponding figures for 1924, which were 18 and 52.

Inspector of Vivisection Laboratories.

Mr. BROMLEY asked the Home Secretary whether Lieut.-Colonel Lelean was still acting as inspector of vivisection laboratories under the Act; whether he had recently paid a visit to University College in that capacity; and whether he himself was the former holder of a vivisection licence.—Captain HACKING replied: Colonel Lelean resigned his post as inspector on Feb. 14th last. The rest of the question, therefore, does not arise.

Education Authorities and Physically Defective Children.

Mr. ROBERT MORRISON asked the President of the Board of Education how many local education authorities had made complete provision for the number of physically defective children under their jurisdiction; how many had made partial provision; and how many had not yet made any provision.—Lord E. PERCY replied: The question whether complete provision exists in any particular area for dealing with physically defective children is a matter of opinion, as it depends upon the thoroughness of ascertainment and on the nature of the standards adopted. In

263 areas provision is made for the education of substantial numbers of physically defective children at special schools, and in about 140 areas provision is made for the treatment of cripple children by way of orthopædic or similar schemes. In about 40 areas no provision has so far been made.

Mr. ROBERT MORRISON asked the President of the Board of Education the present estimated number of physically defective children who might benefit by admission to special schools; how many of these children were at present in special schools; how many in public elementary schools; how many in other institutions; and how many were not attending any school.—Lord E. PERCY replied: The total number of children ascertained by local education authorities in 1925, the latest year for which complete returns are available, as physically defective within the meaning of Section 55 of the Education Act, 1921 (including those suffering from some form of tuberculosis, those classed as cripples, and those classed as "delicate"), was 142,889. Of these, 25,769 attended special schools during that year, 94,332 were at public elementary schools, and 3857 were in other institutions, while 18,931 were not attending any school. As regards the children attending public elementary schools, it should be remembered that most of the delicate children require only a relatively short period at an open-air school, and the majority of the cripples can be so far benefited by orthopædic treatment as to render them capable of profiting from the instruction in ordinary elementary schools.

Approved Societies and Dental Fees.

Mr. RHYS DAVIES asked the Minister of Health whether his attention had been drawn to the fact that several large approved societies in Lancashire, providing dental benefit for their members, had refused to adopt the scale of fees and conditions of service as agreed upon by the Dental Benefit Joint Committee; that a considerable number of dentists had indicated their willingness to continue to do the work on the old scale of fees; that the Public Dental Service Association had in consequence informed such dentists that they were liable to be struck off the Dental Register by the Joint Dental Board; and what action he proposed to take in this matter.—Mr. NEVILLE CHAMBERLAIN replied: I am aware that a few approved societies in Lancashire and elsewhere are still reluctant to adopt the new scale of fees and conditions of service for dental benefit, and that some of them claim that they have obtained from a number of dentists an indication of willingness to accept a lower scale of fees. The opposition to the new scale is, however, daily growing less, as the advantages of the new arrangements drawn up by the Dental Benefit Joint Committee become more fully appreciated. As regards the third part of the question, I am informed that the Public Dental Service Association has called the attention of dentists to a warning notice issued by the Dental Board against anything in the nature of canvassing by or on behalf of dentists with a view to securing work by an offer to accept fees below those of the new agreed scale. I do not think that the circumstances call for any action on my part.

Health Insurance Contributions and Benefits.

Mr. THURTLE asked the Minister of Health if his department was in a position to state the amount of money paid by way of contributions to the health insurance scheme from the date of the Armistice to the year ending Dec. 31st, 1925; and the amount actually paid out to insured persons by way of benefits during the same period.—Mr. NEVILLE CHAMBERLAIN replied: The amount of money paid by way of contributions to the health insurance scheme in England and Wales for the seven years from Jan. 1st, 1919, to Dec. 31st, 1925, was £154,000,000. Of the amount of £143,000,000 spent on benefits in England and Wales during the same period, £86,000,000 represents amounts actually paid out to insured persons by way of benefits, and £57,000,000 the cost of medical benefit provided for them through insurance committees. The information asked for as respects the part of the year 1918 subsequent to the date of the Armistice is not available, as such statistics are compiled for complete calendar years only.

FRIDAY, DEC. 10TH.

Anterior Poliomyelitis after Vaccination.

Mr. GROVES asked the Minister of Health if he would make inquiries as to why no mention of vaccination was made on the death certificate of the young man of 19, whose name had been privately given to his department, who recently died from acute anterior poliomyelitis 14 days after vaccination.—Mr. NEVILLE CHAMBERLAIN replied: The certification of the cause of death is a matter which rests entirely with the medical practitioner in attendance. Inquiries have, however, been made into the circumstances associated with the death in question, and I am informed that vaccination was not entered on the death certificate because in the opinion of the certifying practitioner vaccination was not a primary, secondary, or contributory cause of death.

MONDAY, DEC. 13TH.

THE CORONERS (AMENDMENT) BILL.

The Coroners (Amendment) Bill was considered on Report.

Mr. GATES moved a new clause on behalf of the London County Council, providing that whole-time coroners appointed after the passing of the Act should make contributions towards their pensions at the rate of 5 per cent. of their salaries, and that they should be paid pensions calculated according to their length of service.

As there was no seconder, the amendment fell through.

Mr. PALING moved to omit Clause 23, which provides for fees to medical witnesses who, at the request of a coroner, make a post-mortem examination or attend an inquest. He said that Mr. Cook, a trade-union secretary, had gone to Moscow to bring back some new trade-union ideas. He was not sure that Mr. Cook would not do better if he went to the British Medical Association.

Lieut.-Colonel FREMANTLE: He would learn patriotism.

Mr. PALING said that he only moved the amendment to call attention to the difference in the treatment accorded to the doctors and the miners. He did not object to the Bill giving doctors increased remuneration for attending inquests. They probably deserved it.

Captain HACKING (Under Secretary for Home Affairs) said that the effect of the amendment would be that medical men would not get any fees at all.

Mr. RHYS DAVIES said that the amendment was put down as a protest against the manner in which the increase of fees had been made in committee. He asked if there were not some communications between the Home Office and the British Medical Association in the first instance as regarded the amount of fees to be inserted in the Bill.

Lieut.-Colonel FREMANTLE denied that there had been any machinations between the Government and the British Medical Association. He had personally come into the House of Commons untrammelled by any responsibility to the British Medical Association. He only supported an increase of medical fees in so far as he thought that it could be justified by the needs of the case from the point of view of the State. In this instance he and other of his hon. friends had not accepted the proposals made by the British Medical Association, and had put forward other proposals. They had a very hard job to convince the representative of the Home Office of the necessity and right of their case.

Dr. VERNON DAVIES protested against the attack made on the medical profession by the mover of the amendment. It was entirely unnecessary to make a comparison between medical men and miners. Speeches of that kind were apt to give a very wrong impression. Anything which endangered the good feeling between medical men and their patients was detrimental. If a guinea was a fair fee in 1844, surely at this time there should be some slight increase. There was a tendency in the Labour party to belittle the medical profession, and the harm that might do in the country might be very great.

The amendment was negatived.

The report stage was concluded.

On the motion for the third reading, Mr. RHYS DAVIES said that the Labour party had a very high regard for the medical profession.

In reply to questions, Captain HACKING said that the Home Secretary would direct coroners to allow trade-union representatives to attend inquests, and to allow medical men representing relatives to be present at post-mortem examinations.

The Bill was read the third time.

Vivisection Experiments on Dogs at University College.

Sir ROBERT GOWER asked the Home Secretary the number of dogs which had been used for vivisectional experiments at the University College School of Physiology during the past two years; and how many of such dogs had been used for vivisectional demonstrations before students.—Captain HACKING replied: 1147 dogs have been used for experimental purposes at University College during 1925 and 1926. Of this number 21 were used for demonstrations before students. By Section 3 of the Act it is laid down that experiments for this purpose may only be performed if a certificate is given by two of the scientific authorities specified in the Act that the experiments are absolutely necessary for the due instruction of the students, with a view to their acquiring physiological knowledge, or knowledge which will be useful to them for saving or prolonging life or alleviating suffering. Such experiments are required to be performed under anæsthetics, and the animals must be killed before recovering consciousness. All but 28 of the total number of animals were kept under anæsthetics during the whole of the experiment and destroyed before recovering from the anæsthetic.

Spahlinger Tests on Cattle.

Mr. HURD asked the Minister of Agriculture if his department had received a copy of the Report of the Geneva

State veterinary surgeons recording the success, which they stated to be beyond all hopes, of the Spahlinger tests now completed there with antituberculosis vaccine on cattle; and whether he contemplated any further steps to estimate the value of these reported results.—Mr. GUINNESS replied: The Ministry's knowledge of the tests of Mr. Spahlinger's vaccine which have recently taken place in Switzerland is limited to accounts which are published in the Press. In 1924 a committee was formed, under the chairmanship of Commander Bayley, R.N., which included prominent agriculturists, doctors, and veterinary surgeons. I am informed that this committee had complete plans for experimental trial of the vaccine, but was unable to obtain any vaccine from Mr. Spahlinger, and therefore the matter dropped. I understand that the committee is still in being, but I am unable to say whether it will be prepared again to undertake the trial of this vaccine.

Enforcement of Food Preservative Regulations.

Mr. TINNE asked the Minister of Health whether he was aware that the recent industrial unrest had diminished the demand for canned goods, and left traders with stocks which would otherwise have been absorbed; and would he postpone till June 30th the enforcement of the Public Health (Preservatives in Food) Regulations, 1925, so far as concerned canned peas and beans and Californian evaporated fruits.—Sir KINGSLEY WOOD replied: My right hon. friend has received representations to the effect stated in the first part of the question, and he proposes to deal with the matter by suggesting to local authorities that during the first part of 1927 they should abstain from proceeding under the regulations where reasonable attempts have been made to dispose of old stock.

Origin of Small-pox Cases in Brondesbury.

Mr. LANSBURY asked the Minister of Health whether the two small-pox patients who were removed to the Willesden Isolation Hospital from a nursing home in Brondesbury, on or about Oct. 29th last, had been vaccinated; how long these patients were under medical treatment in London before it was discovered that they were suffering from small-pox; whether it was now possible to say where these persons came from on their arrival in London; and what steps had been taken to trace the origin of the disease.—Sir KINGSLEY WOOD replied: My right hon. friend is informed that both these patients had been vaccinated; the interval between vaccination and attack by small-pox was approximately 26 years in one instance and 44 years in the other. In one instance the patient was under medical treatment for 19 days, and in the other for four days, before a diagnosis of small-pox was made. Both persons had been staying in Paris before their arrival in London, and the first case was presumably infected in France, while the second case was a contact with the first.

Government and Washington Hours Convention.

Mr. BENJAMIN SMITH asked the Minister of Labour whether, in view of the change in the industrial situation, it was the intention to proceed forthwith with the ratification of the Washington Hours Convention.—Mr. BETTERTON (Parliamentary Secretary to the Ministry of Labour) replied: As stated on Dec. 8th, it is the intention of the Government to consider, as soon as they conveniently can, the results of the London Conference and their bearing upon the question of the ratification of the Washington Hours Convention. Until that consideration has been given, I am unable to make any further statement in the matter.

Family Pension Scheme for All-India Services.

Mr. HAYES asked the Under Secretary of State for India whether a State contribution was provided for in the family pension scheme now under the consideration of the Government of India for the All-India Services other than the Indian Civil Service; and, if so, whether this State contribution was to be similar to that granted to the Indian Civil Service Family Pension Fund.—Earl WINTERTON replied: A Family Pension Scheme for European members of the All-India Services, including the Imperial Police Service, is at present under the consideration of the Government of India. The Government of India's views have not yet been received, and I regret that I cannot give any details of it at present. The services affected will be consulted before any scheme is brought into operation.

TUESDAY, DEC. 14TH.

Vivisection Experiments on Dogs and Cats in London.

Sir ROBERT GOWER asked the Home Secretary how many dogs used for vivisectional experimental purposes in registered premises in the London area since Jan. 1st of this year were not kept under complete anæsthesia during the whole time of the experiments; the nature of the experiment on each of such dogs; at which schools of physiology such experiments were respectively made; whether reports had been received from the authorities of such schools giving the reasons why such animals were not kept under complete anæsthesia during the continuance of the experiments; and what such reasons were.—Captain HACKING replied: 16 at University College, 5 at the Brown Institution. I cannot undertake to give details of individual experiments, but I may say that the object of the experiments was in 7 cases the investigation of dental diseases, in 5 insulin research, in 4 investigation of diseases of the tonsils, and in 5 investigation of the relation of the gall-bladder to intestinal diseases. The last part of the question appears to be based on a misapprehension. The Act requires no such reports as are mentioned; what it does require is that before any experiment can be performed which involves keeping the animal alive after it recovers from the anæsthetic a certificate must be given by two of the scientific authorities mentioned in the Act to the effect that killing the animal before it so recovers would necessarily frustrate the object of the experiment; and further, that before any such experiment is performed on a cat or dog, an additional certificate must be given by two of the same scientific authorities that for specified reasons the object of the experiment will be necessarily frustrated unless it is performed on an animal similar in constitution and habits to a cat or dog, and that no other animal is available for such experiment. These certificates were duly given in each of the cases mentioned above.

Young Man's Death after Vaccination.

Mr. BRIANT asked the Minister of Health whether the case of the young man of 19 who recently died about 14 days after vaccination, the name of whom had been given privately to him in a letter, dated Nov. 19th, from Mr. Arnold Lupton, had been reported to the Committee on Vaccination now sitting.—Sir KINGSLEY WOOD replied: Yes, sir.

Ministry of Pensions Appointments.

Mr. DENNISON asked the Minister of Pensions whether he intended to make further appointments of established officers in substitution for officers of the P class as area and deputy chief area officers; and what was the estimated extra cost to public funds of this policy during the current financial year.—Lieut.-Colonel G. F. STANLEY replied: It may be necessary from time to time to effect transfers of established officers to other posts in the Ministry as the fall in the volume of work may necessitate, as it is not administratively possible to exclude area offices from the field of consideration for such transfers. There is no additional charge on public funds involved in the appointments to which the hon. Member refers, the established officers mentioned having become available for appointment in area offices in consequence of savings effected in other branches of the Ministry.

PENSIONS FOR HOSPITAL STAFFS.—The General Council of King Edward's Hospital Fund for London has now decided that in making annual grants to hospitals they will take into account the amount spent on contributory pensions schemes. The draft scheme, based on the report of a special committee under the chairmanship of Mr. W. J. H. Whittall in 1919 (THE LANCET, 1926, i., 679 and 729), has continued to make progress since the Mansion House Conference of May 19th last. On July 5th a Provisional Council was formed comprising representatives of 69 hospitals and by Nov. 1st 88 hospitals had joined, representing 11,579 beds. Quotations are now to be invited from insurance companies for the various benefits contemplated. The annual premium is to be 15 per cent. of salary and emoluments (the latter being roughly the money value of board and lodging), two-thirds to be paid by the hospital and one-third by the individual. The policies are to mature at the age of 60, so that retirement can take place then or later in accordance with the regulations of the hospital concerned. The Provisional Council has defined the institutions eligible for participation in the scheme as follow: (*a*) voluntary hospitals; (*b*) consumption sanatoriums; (*c*) hospitals for incurables; (*d*) convalescent homes; (*e*) dispensaries; (*f*) King Edward's Hospital Fund for London, the Metropolitan Hospital Sunday Fund, the Hospital Saturday Fund, and the Hospital Saving Association; (*g*) private hospitals, mental and others, not run for profit; (*h*) the Incorporated Association of Hospital Officers; (*k*) nurses' coöperations, incorporated and approved; (*l*) Queen Victoria's Jubilee Institute for Nurses and affiliated associations and branches; (*m*) Ranyard nurses; (*n*) voluntary welfare centres; (*o*) the College of Nursing and the Royal British Nurses' Association; (*p*) such other kindred classes of institution as the Provisional Council may determine—and Sir Edward Penton, chairman of the Provisional Council, hopes that the premium rates may be settled early in the new year so that the scheme may then be ready for launching.

Medical News.

UNIVERSITY OF LONDON.—At examinations held recently the following candidates were successful :—

THIRD (M.B., B.S.) EXAMINATION FOR MEDICAL DEGREES.

With Honours.—Alexander C. Dalzell (*b*, *e*), Lazarus Hartston (*a*), Maurice Mitman (*a*, *d*), and Gerald H. Steele (*a*, *d*, University Medal).

(*a*) Distinguished in Medicine. (*b*) Distinguished in Pathology. (*d*) Distinguished in Surgery. (*e*) Distinguished in Midwifery.

Pass.—Dorothy R. Adams, Clifford E. Allen, Harold Awrounin, Shriharsh Chintaman Bakhle, James R. Beagley, Samuel A. Beards, Louis F. Beecle, Eric H. J. Berry, Edith D. Bowie, Robert J. Cann, Rose A. Carter, Evangeline A. Clark, John S. Coleman, Hugh A. Cooper, Arthur C. Counsell, Anne A. Craig, Samuel S. Cruden, Howell J. Davies, Muriel Davies, Doris L. Delittle, John C. G. Dickinson, John D. Durance, Elaine Œnone H. Earengey, Donald C. Fairbairn, Maurice Fishman, William Fletcher-Barrett, Wilfred F. Gaisford, Stanley C. Gawne, Percy L. Goitein, Minnie Gosden, Charles R. M. Greenfield, James I. Griffiths, Reginald D. Gross, Leslie W. Hale, John G. Hamilton, Kempton P. Hare, Richard B. Hawes, William E. Heath, Frances M. Heaton, James C. Heweston, Norman G. Hill, Frederick D. M. Hocking, David P. Holmes, Benjamin B. Hosford, Douglas V. Hubble, Amelia M. Ison, Clifford James, Herbert N. James, Iorwerth H. Jones, Robert O. Jones, Isabel M. Jordan, Gladys Kay, Greta M. Langdon, Reginald H. Leigh, Reginald H. Little, George K. Loveday, Elsie Lyons, Margaret B. MacDonald, Norman W. MacKeith, Evelyn T. D. Maclagan, Douglas H. McLeod, Ian McPherson, Dorothy B. Marling, Mary A. Marshall, Stephen K. Montgomery, John G. Morgan, Dorothy L. Neate, George J. V. Nelken, George A. H. Norman, Herbert L. Oldershaw, Catherine E. Orr-Ewing, Evelyn M. Pakeman, William E. Parry, Charles E. Pearsons, Arthur D. Pegg, George E. G. Peirce, Louis M. J. R. Pilot, Isaac Price, Henrietta Procter, Muriel F. Prout, Daniel M. Pryce, Bertine M. Rix, Lewis H. Savin, Jacobus W. Schabort, Jonathan A. Screech, Eric C. Seward, Mary M. Sillito, Alan S. Simpson, Anthony J. D. Smith, William E. Snell, Ivor P. Spurrell, Eustace F. Stead, Edith A. Straker, Stephen V. Strong, Daniel E. Thomas, James D. S. Thomas, Oxburgh G. Tippett, John R. Tree, Betty C. Waters, Edith M. Webb, Arthur S. Wesson, Violet M. Weston, Edward A. White, Doris Williams, Jane C. Williams, Emily A. C. Wilson, Herbert F. Wilson, and James T. Wybourn.

The following students have passed in one of the two groups of subjects :—

Group I.—Douglas E. Barton, Doris D. Brown, Isabella M. G. Butler, Irene F. Callender, Tom E. Davies, Arthur E. de Chazal, Jean M. Dollar, Joel Gabe, Allen C. Hancock, Lynette Hemmant, Mary H. McC. Huggett, Rowland M. Jones, Eileen M. King, Miriam A. Lawson, William Leslie, Albert H. Levers, Michael F. B. Lynch, Barbara H. Mitchell, Doris Reynolds, Sibyl D. Rodgers, Ephraim S. Rudaizky, Margaret V. Saul, and Horace S. Townsend.

Group II.—William A. Ball, Arthur L. Banks, Raymond E. Barrett, Hilda M. P. Bond, Derek G. Bown, Denis A. Brigg, Helen M. Browne, Maurice R. Burke, Alfred L. Canby, Donald C. MacC. Ettles, John Evans, Leonora S. Evans, Bernard W. Goldstone, Donald P. Gray, Henry F. Hiscocks, Laurence Holmes, John G. Kingsbury, Edgar D. Lawrence, Joan J. Lush, Alexander C. MacLeod, Charles W. Marshall, Hakim M. Mikhail, Anna P. Momtgomery, Reginald T. Payne, Alice L. Robson, Edward H. Roche, Moses Sendak, Kenneth S. Smith, James E. Swyer, Mary C. Tugman, Mary M. Tulloch, John S. Whitton, Beatrice A. Wilkinson, Harry K. Williams, and Eric Wornum.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At a meeting of the Council, held on Dec. 9th, Sir Berkeley Moynihan, the President, in the chair, the resolution carried at the annual meeting of Fellows and Members, asking the Council to take a postal vote of Fellows and Members on the question of admitting Members to direct representation on the Council of the College, was referred to a Committee for consideration.—Mr. E. Rock Carling, surgeon to the Westminster Hospital, Mr. A. E. Webb Johnson, surgeon to the Middlesex Hospital, and Mr. Claude Frankau, surgeon to St. George's Hospital, were elected Members of the Court of Examiners. Mr. C. H. Howkins, dental surgeon to the Birmingham Dental Hospital, was elected a Member of the Board of Examiners in Dental Surgery.—Sir Berkeley Moynihan was reappointed a representative of the College on the Court of Governors of the University of Birmingham, and Mr. Victor Bonney was appointed a representative of the College on the Central Council for District Nursing in London.—Diplomas of Fellow were conferred upon 27 candidates who passed the recent examination. Of 101 candidates presenting themselves for examination, 31 passed, but R. A. Brews (London), C. I. N. Morgan (St. Bart.'s), F. T. Ridley (Birmingham and London), and A. J. Wrigley (St. Thomas's and Guy's), who satisfied the examiners, are not eligible to receive the diploma until they have attained the requisite age. The following are the names and medical schools of the successful candidates :—

N. Asherson, Univ. Coll. ; T. S. M. Barnett, Melbourne and Guy's ; W. E. Barnie-Adshead, Birmingham and Guy's ; R. C. Brown, Durham and London ; E. A. Coldrey, St. Bart.'s ; W. I. Daggett, Cambridge and King's Coll. ; V. W. Dix, Cambridge and London ; S. J. H. Griffiths, Bristol, Guy's, and London ; A. J. C. Hamilton, Edinburgh and London ; C. W. Harris, Toronto and London ; P. R. Hawe, Liverpool ; K. W. Heritage, London ; A. L. P. Jeffery, St. Thomas's ; P. Kiely, Cork and London ; A. C. King, London ; P. B. Kittel, Cambridge and St. Bart.'s ; E. D'A. McCrea, Dublin ; F. A. MacLaughlin, Belfast ; P. Malpas, Liverpool and London ; J. M. D. Mitchell, Aberdeen and St. Bart.'s ; M. F. Nichols, Guy's and St. George's ; K. O. Parsons, Guy's ; G. D. Robb, Otago ; J. S. Rowlands, Liverpool and Univ. Coll. ; I. G. Sacks, Dublin ; and L. H. Savin, King's Coll.

Diplomas of Member were conferred upon the following :—

A. C. Jepson, Cambridge and Guy's ; P.N. Lahiri, Calcutta and Guy's ; and L. A. Richardson, Cambridge and St. Thomas's.

Licences in Dental Surgery were conferred upon the following 83 candidates :—

L. R. Armstrong, S. K. Arnold, J. G. Avent, L. G. Baker, H. Bennison, M. Bewlay, I. Bishko, S. D. Bradley, E. J. Buxton, L. Catchpole, O. N. Catchpole, E. H. Clark, M. H. C. L. Clutterbuck, W. J. Coe, E. C. Councell, Mary E. O. Cross, Eileen M. Currie, R. G. Daplyn, E. N. Davey, D. G. Doran, H. W. Duchesne, C. M. Duckworth, N. S. Farnes, J. E. Forrest, I. Frankel, W. F. Fuller, Beryl Gardiner, G. D. Gibling, G. G. Grainger, R. Y. Greenfield, D. Gure, R. T. Hale, H. R. Hill, C. Hofman, S. S. How, L. H. Ide, H. O. B. James, H. W. Johnson, K. S. Keele, K. S. Law, H. P. Lawson, K. Lees, M. Lewis, A. Livingston, M.B., Ch.B., Marjorie E. E. Lodge, L. S. Lyons, A. McEwen, L. J. Martin, G. H. Mason, H. A. Mills, D. Morrison, E. R. Morten, L. G. W. Papenfus, M. M. Pellatt, G. R. Pidgeon, S. C. Post, G. Quinn, G. Radloff, P. C. Ranye, J. A. Reader, H. E. Rose, C. A. Rumball, J. J. Sanders, Luba Scott, G. J. C. Sem, A. Simaika, C. Skinner, E. S. Smith, Dorcas E. Sproulle, J. Stazunsky, J. W. Storey, C. T. Tayler, H. E. C. Terry, D. F. Turner, S. E. Wallis, J. Weakley, C. Welt, C. R. Wilshaw, C. K. Wilson, W. A. Wilson, H. W. Wright, H. S. Wright, and H. H. Wydell.

UNIVERSITY OF SHEFFIELD.—The following have passed the Final Examination for the degree of M.B., Ch.B.: George H. Arnison and Edna M. Stedeford.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.—The annual meeting of the College was held on Dec. 2nd. Dr. George M. Robertson was re-elected President for the ensuing year ; Sir Robert Philip was nominated Vice-President ; and Dr. G. Lovell Gulland, Dr. R. A. Fleming, Dr. Robert Thin, Dr. John Orr, and Dr. Edwin Matthew were re-elected to form the Council. At an extraordinary meeting held on the same day, Dr. Edward Arnold Carmichael and Dr. John Robert Lord were elected Fellows of the College. Dr. William Russell and Dr. John Orr were elected representatives on the Board of Management of the Royal Infirmary of Edinburgh.

UNIVERSITY OF MANCHESTER.—At examinations held recently the following candidates were successful:—

FINAL M.B. AND CH.B. EXAMINATION.

Helen G. M. Bennett, Pieter Bester, H. V. Crabtree, Margaret Egan, Ernest Firth, Ernest Heard, John Hunt, G. W. Jones, Joseph Parness, Harry Pigott, R. H. Poyser, Mary I. Prentice, Leonard Rosenthal, B. R. Sandiford, W. S. Slater, Donald Starr, and Florence V. Stephen.

The following candidates satisfied the examiners in the subjects indicated :—

Forensic Medicine.—Soloman Bernstein, Vera Urmson, and G. R. Walker.

Medicine.—G. R. Walker.

Hygiene and Preventive Medicine.—R. H. Barnes, Soloman Bernstein, Ralph Edmondson, Dorothy Guest, James Kemp, G. L. Normington, L. C. Peringuey, I. M. Preston, Nora Ridehalgh, R. F. Sheppard, R. H. Tootill, and Vera Urmson.

Obstetrics and Surgery.—R. S. Abraham, Dorothy Arning, Harold Arstall, A. H. Baker, Doris Bernard, Dorothy M. Bradley, Muriel M. Edwards, Arthur Hancock, G. D. Hithersay, J. H. Jones, James Kemp, H. E. Martin, Robert Newton, R. P. Osborne, H. A. Palmer, G. H. Racklyeft, Norah Regan, Marshall Robinson, Leonard Rosenthal, Eleanor B. Schill, Herbert Townley, F. F. Waddy, Josephine Walmsley, and K. H. Watkins.

Obstetrics.—S. K. Appleton, H. J. Brennan, S. L. Rowley, and Alfred Thomas.

THIRD M.B. AND CH.B. EXAMINATION.

Pathology.—M. M. Barritt, G. L. Brown (with distinction), Alice M. Butterworth, Alexandra W. Groves, J. H. Pattyson, Marian M. Reekie, J. F. Wilkinson, and Frederick Wraith.

Pharmacology.—Alexander Allan, H. S. Bagshaw, F. H. Bentley, Hedley Boardman, Edith M. Booth (with distinction), B. R. Bramwell, R. O. Brooks, J. A. K. Brown, Bessie H. E. Cadness, T. H. Chadwick, D. L. Cran, J. M. Greenwood, Christobel M. Hall, G. B. Hardman, W. H. Harris, E. Z. Levy, R. W. Luxton, Mary I. C. Mackintosh, A. S. McGowan, F. N. Marshall, A. B. Moffatt, W. H. Newton, J. R. Nuttall, H. J. O'Loughlin, J. H. Pattyson, G. W. Plowright, B. P. Robinson, Donal Sheehan, C. F. Stott, J. D. Todd, Nellie Wilson, and L. C. Wright.

MEDICO-LEGAL SOCIETY.—The annual dinner of this society was held on Dec. 10th at the Holborn Restaurant, with the President, Lord Justice Atkin, in the chair. Dr. A. S. Woodwark proposed the toast of "Medicine and Law," Sir John Rose Bradford replied for the medical, and Dr. A. H. Coley, President of the Law Society, for the legal profession. Mr. Justice Greer, proposing the toast of "The Medico-Legal Society," mentioned how closely the respective sets of problems of the two professions resembled one another. Doctors had often to diagnose on subjective symptoms, without being able to see inside the patient, and judges had to decide cases on evidence that might be imperfect or even dishonest. Two of the most important subjects of common interest to both to-day were those of the effects of nervous shock and of insanity. So far from medical witnesses being reluctant to give a plain "Yes" or "No," they were often positive when they should say, "Neither I nor anybody else can tell." The question of nervous shock and its effect was a typical one in which positive assertion was to be avoided. For his part he was always inclined to give the subject the benefit of the doubt. Doctor and lawyer were alike handicapped by not being able to see the sufferer as he would be five years afterwards. In their attitude to mental disease doctors and lawyers had taken up very different positions, but there was not so much difference between them as might at first sight appear. The issue to be decided by trial was not whether a man was suffering from mental disease, but whether that disease was of such a character that he could not be held responsible for his acts, or, under the McNaghten ruling, that he either did not know the nature and quality of his acts or, if he did, that he did not know he could be punished for them. The law had to be laid down with great strictness, and modified where necessary by those whose duty it was to advise His Majesty when to exercise the Royal prerogative. Juries were somewhat inclined to sympathy with the medical view and the "unwritten law," and he saw no case for relaxing the law as at present laid down. Lord Justice Atkin, in responding for the Medico-Legal Society, remarked that the distinction between insanity and "legal insanity" was one drawn by very few people in fact, but that there must be a degree of insanity fixed by law as a boundary between criminal responsibility and irresponsibility. It was important to abstain from language that might emphasise the difference in the views held by each profession. Not long ago a high judicial authority had denounced as fantastic the view that a person who committed a crime under an irresistible impulse produced by disease should be held irresponsible. On the contrary, that doctrine was unanswerable. The committee over which he presided had accepted it, and lawyers such as Sir Archibald Bodkin, the late Sir Richard Muir, Sir Herbert Stephen, and Sir Ernley Blackwell were not likely to hold "fantastic" views on any subject. His lordship also suggested that much good would result if doctors and lawyers could hear lectures from one another on the administration of the Workmen's Compensation Act. The toast of "The Guests" was proposed by Dr. R. Henslowe Wellington and answered by Lieut.-Colonel C. T. Samman, Junior Warden of the Apothecaries' Society, and Mr. A. MacMorran, K.C., the Treasurer of the Middle Temple.

DINNER TO SIR BERKELEY MOYNIHAN.—On Dec. 8th Sir Berkeley Moynihan was entertained to dinner at Leeds by the British Medical Association in Yorkshire. Mr. Alfred Gough presided, and in proposing the toast, "The President of the Royal College of Surgeons," said that for at least a quarter of a century Sir Berkeley Moynihan had been one of the most prominent figures in British surgery. His election to the Presidency of the Royal College of Surgeons did not amount to the conferment of a distinction, but rather to the recognition of a distinction. Mr. A. L. Whitehead recalled the time when Sir Berkeley Moynihan was a student at the old Leeds Medical School. When he went to the Leeds Infirmary he had found there a wonderful group of surgeons—Jessop, McGill, Ward, and Littlewood. The only one of the group remaining was the greatest of them, Sir Arthur Mayo Robson. It might be said of Moynihan that he had acquired the best from all of them. At first he had had a hard struggle and some disappointments, but his book, "Abdominal Surgery," had aroused interest all over the world, and his work had received wider and wider recognition. Perhaps the qualities which most helped him to become a successful surgeon were his insistent attention to detail, combined with a wide general outlook, and his insistent desire to improve technique. His powers of expression would have made it easy to leave surgical practice for literature or politics, but fortunately those temptations had been resisted. The magic of his tongue had always been at the disposal of those with a righteous cause, and his last effort, his appeal for the Cancer Research Fund, which had resulted in raising the magnificent sum of £130,000, had been marvellous. Some great men engrossed in their work seemed to be devoid of humanity, but as Sir Berkeley Moynihan had grown as a surgeon he had also progressed as a man. Dr. A. Hawkyard said that no one citizen of Leeds had ever made the city so famous as had Sir Berkeley Moynihan. Apart from his eminence as a surgeon he was one of the first six orators in this country. Sir Berkeley Moynihan, in reply, said that however diverse the roads travelled, the goal reached at the end was very likely to be the same. In his cradle he had been dedicated to the Army, but he had chosen the perhaps less glorious but more remunerative path of saving life rather than of destroying it. Had he joined the Army, escaped death, and won distinction, he would have been made a Major-General in the very same month as this rank was actually conferred on him. In his student days nothing was less conceivable than that a student of the Leeds School of Medicine—perhaps the humblest and poorest student in the school—should have been the first surgeon outside London to be made President of the Royal College of Surgeons. He felt that he owed everything to Jessop and McGill. He thought he cause of surgery was advanced by men who served it rather differently. There were, in the first place, the men of genius, of great original creative minds, who made the great generalisations, who had the force to put ideas in motion. Then there were those who could capture the new idea almost at the moment of its birth, and make it marketable in all the countries of the world; they were the apostles of the new faith. And then there were the men who kept the thing going. They had perhaps no great gifts except the gifts of the craftsman; on the stage of surgery they were rather actors than authors. The pre-eminence of Leeds in surgery—for there was a pre-eminence of Leeds in surgery—had been due to the fact that it had produced one or two men entitled to be placed in the first category—Spencer Wells, William Hey, and, he almost thought, Mayo Robson, who was the incomparable surgeon of his time; it had produced many men of the second category and comparatively few of the third. Leeds had taken its place as a school of surgery second to none. Sir Berkeley Moynihan went on to speak of the reciprocity between surgeons in the North of England and of the *Journal of Surgery*. There were those who said that the generation just coming to an end had had great luck. So they had, and they had done the best they could with it. He thought the Listerian epoch was over; but he thought the future incalculably brighter than the past had been. Surgery was now the safe weapon for research and if that were true, how was surgery to advance? It could only advance by going back to the beginning of things again, by harking back to biology in its broadest sense, by going hand-in-hand with physicists, biochemists, chemists, and physiologists. In conclusion, Sir Berkeley Moynihan said that their tribute to him had touched him deeply as a tribute to something he valued much more—to the great tradition that Leeds had set up a century and a half ago and had never allowed to weaken since.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—The Fellowship has arranged the following special courses for January. From Jan. 10th to 22nd the Prince of Wales's General Hospital, Tottenham, will hold an intensive course in medicine, surgery, and the specialties. The daily sessions will last from 10.30 A.M. to 5.30 P.M. On Jan. 10th a two weeks' combined course in diseases of children will begin at the Royal Free Hospital and the Children's Clinic. From Jan. 11th to Feb. 5th there will be a series of lecture-demonstrations on psychological medicine on Tuesdays and Saturdays at 11 A.M. at the Bethlem Royal Hospital. From Jan. 17th to 29th an intensive course in cardiology will be held at the National Hospital for Diseases of the Heart. As entry to this course is limited to 20, early application is desirable. Courses in obstetrics, lasting two weeks or a month, can be arranged at the Queen Charlotte's Hospital. Every week the City of London Maternity Hospital holds a course in obstetrics and child welfare, personal application for which must be made to the office of the Fellowship, which can also arrange for clinical assistantships at the Samaritan Hospital. The series of lectures on Emergencies in Medicine and Surgery will begin again on Jan. 27th. Demonstrations in clinical surgery and ophthalmology will also be resumed in January. Syllabuses of the special courses and copies of the programme of the general course and of the *Post-Graduate Medical Journal* may be had from the Secretary of the Fellowship, at 1, Wimpole-street, London, W. 1.

BRITISH MEDICAL ASSOCIATION.—At 8 P.M. on Monday, Jan. 24th, 1927, Sir Berkeley Moynihan will deliver the Hastings Lecture in the Great Hall of the British Medical Association. His subject will be Cancer and How to Fight It, and Mr. Neville Chamberlain, Minister of Health, will take the chair. Admission will be free by tickets obtainable on application to the Financial Secretary, B.M.A. House, Tavistock-square, London, W.C. 1.

IRISH FREE STATE AND THE MEDICAL REGISTER.—President Cosgrave made a brief announcement in the Dail last week dealing with the question of the Medical Register. He said that it might be necessary before the Christmas adjournment to give notice of the extension of the Medical Act for three months. Nevertheless, it might not be necessary to take the full three months, as agreement was practically achieved, and they were now working out details.

NEW DEWSBURY INFIRMARY. — Dewsbury and District Infirmary, which serves a large area, is no longer adequate to the demands upon it, and it has been decided to erect a new building on an eminence overlooking the town. The cost is estimated at £90,000, of which one-half is in hand. The existing hospital has 60 beds ; the new one will contain 101, but the plans provide for future extensions up to 150 beds. There will be a nurses' home to accommodate 50 members of the nursing staff.

ROYAL NORTHERN HOSPITAL.—It is announced that series of post-graduate courses are to be held at the Royal Northern Hospital, Holloway-road, London, N.7, beginning on Tuesday, Jan. 4th, 1927, and continuing throughout the year except during the months July, August, and September. Two sets of courses will be held : the first will be open to all practitioners, free of charge, and will consist of (1) weekly lectures or demonstrations on Tuesdays at 3.15 P.M., and (2) intensive courses, lasting one week, to be held in February, May, and October. The second course, on Recent Advances in Medicine, is designed for practitioners preparing for higher medical examinations. This will be held three times a year, the first being arranged for next March, and a fee of 5 guineas will be charged. Full particulars of these courses may be had from the Dean of the Hospital, Dr. E. G. B. Calvert.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, Dec. 20th.—10 A.M., Mr. Macdonald : Genito-Urinary Operations. 12 noon, Mr. Simmonds : Fractures and Applied Anatomy. 2 P.M., Dr. Scott Pinchin : Medical Out-patients.

TUESDAY.—12 noon, Dr. Burrell : Demonstrations of Chest Cases. 2 P.M., Mr. Addison : Operations. 2 P.M., Mr. Sinclair : Surgical Out-patients.

WEDNESDAY.—10.30 A.M., Dr. Burnford : Medical Wards. 2.30 P.M., Mr. Donald Armour : Surgical Wards. 2 P.M., Dr. Owen : Medical Out-patients.

THURSDAY.—10 A.M., Dr. Grainger Stewart : Neurological Dept. 2 P.M., Mr. Simmonds : Surgical Out-patients. 2 P.M., Mr. Bishop Harman : Eye Dept.

FRIDAY.—10 A.M., Sir Henry Simson : Gynæcological Operations. 10.30 A.M., Dr. Dowling : Skin Dept. 2 P.M., Mr. Vlasto : Throat, Nose and Ear Dept.

Operations, Medical and Surgical Out-patients, Special Departments, daily, 10 A.M. to 5 P.M. Saturdays, 10 A.M. to 1 P.M.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, Dec. 20th.—10 A.M., Surgical Clinic. 2 P.M., Medical Cases in the Wards. 2.30 P.M. to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 P.M. to 5 P.M., Medical, Surgical, Throat, Nose, and Ear Clinics. Operations.

WEDNESDAY.—2.30 P.M. to 5 P.M., Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M., Dental Clinic. 2.30 P.M. to 5 P.M., Medical, Surgical, and Ear, Nose, and Throat Clinics. Operations.

FRIDAY.—10.30 A.M., Throat, Nose, and Ear Clinics. 2.30 P.M. to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.

TUESDAY, Dec. 21st.—5 P.M., Dr. A. C. Roxburgh : Urticaria.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.

WEDNESDAY, Dec. 22nd.—1.45 P.M : Dr. Norman Mackeith : Hearing Tests.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, St. Andrews.

TUESDAY, Dec. 21st.—4 P.M., Major Walter Elliot, M.P., Under Secretary of Health : Clinical Research in its Relation to the Public Health Services. Discussion to be opened by Dr. G. Matthew Fyfe.

Appointments.

DAWSON, WILLIAM S., M.D. Oxf., M.R.C.P. Lond., has been appointed Professor of Psychiatry in the University of Sydney, New South Wales.

HALLCHURCH, W., M.B., Ch.B. Edin., Hon. Medical Officer in Charge of the new Ear, Nose, and Throat Department of the Dudley Guest Hospital, Wolverhampton.

HARRIS, W. H., M.B., Ch.B. Aberd., Assistant Medical Officer of Health for Aberdeen.

Certifying Surgeons under the Factory and Workshop Acts : NEWTON, E., M.R.C.S., L.R.C.P. Lond., D.P.H. (Tilbury) ; MERCER, E. B., M.B., Ch.B. Edin. (Littlebourne, Kent).

Vacancies.

For further information refer to the advertisement columns.

Bedford County Hospital.—Asst. H.S. At rate of £130.

Birkenhead Borough Hospital.—Hon. Radiologist.

Birmingham, Queen's Hospital.—Cas. Surg.

Bury Infirmary.—Second and Third H.S.'s. At rate of £175 and £150 respectively.

Calcutta Corporation.—Health Officer. Rs.1500 per mensem.

Cardiff, University College of South Wales.—Prof. of Anatomy. £1000.

Charing Cross Hospital.—Med. Registrar. £150.

Dagenham Urban District Council.—M.O.H. and Asst. County M.O. £550 and £250 respectively.

Glasgow, Govan District Asylum, Halfwayhouses.—Third Asst. M.O. £275.

Greenwich Metropolitan Borough.—Obstet. Consultants. 3 to 5 guineas per consultation.

Hammersmith, School Treatment Centre, 10, Mall-road, W.—M.O.

Lancaster County Mental Hospital.—Temp. Asst. M.O. 7 guineas weekly.

London Hospital, E.—Vacancy on Hon. Medical Staff.

London Temperance Hospital, Hampstead-road, N.W.—H.P. At rate of £100.

Middlesbrough County Borough Mental Hospital.—Asst. M.O. &c. £550.

Newcastle-upon-Tyne, Princess Mary Maternity Hospital.—Asst. Res. M.O. At rate of £40.

Oxford, Radcliffe Infirmary and County Hospital.—H.S. and Obstet. H.P. Each at rate of £120.

Prince of Wales's General Hospital, Tottenham, N.—Hon. Asst. Radiologist, Physio-Therapeutist. Also Hon. Assts. S.

Reading, Royal Berkshire Hospital.—H.P. and Third H.S. Each at rate of £150.

Rochdale Infirmary and Dispensary.—Jun. H.S. £200.

Royal Army Medical Corps.—Commissions.

Royal London Ophthalmic Hospital, City-road, E.C.—Seven Refraction Assts. £100.

St. Mary Abbots Hospital.—Res. Phys.

St. Marylebone General Dispensary, 30, Marylebone-lane, W.—Hon. Phys.

St. Mary's Hospital, W.—Med. Registrar. £200.

St. Peter's Hospital for Stone, &c., Henrietta-street, Covent Garden, W.C.—Clin. Assts.

Sheffield, Jessop Hospital for Women.—Asst. H.S. At rate of £1000.

Sheffield Royal Infirmary.—H.S. At rate of £80.

Sheffield University.—Dept. of Pharmacology, Research Asst. £600.

Sutton, Surrey, Downs Hospital for Children.—Asst. M.O. £550.

Ventnor, Isle of Wight, Royal National Hospital for Consumption and Diseases of Chest.—Jun. Res. M.O. At rate of £300.

West London Hospital, Hammersmith, W.—Hon. S. to Throat, Nose, and Ear Dept. Also Hon. Obstet. Reg.

Worcestershire County Council.—Asst. County M.O. £600.

The Secretary of State for the Home Department gives notice of a vacancy for a Medical Referee under the Workmen's Compensation Act for the districts of the Denbigh and Ruthin, and Rhyl County Courts. Applications should reach the Private Secretary, Home Office, not later than Jan. 3rd next year.

Births, Marriages, and Deaths.

BIRTHS.

ATKINSON.—On Dec. 2nd, at Stainer-street, S.E., the wife of Dr. C. Hewitt Atkinson, of a daughter.

DANDO.—On Dec. 8th, at Queen's Club-terrace, Kensington, W., the wife of Dr. Dando, of a daughter.

SATOW.—On Dec. 9th, in Oxford, to Margaret, the wife of Lawrence L. Satow, *M.C.*, M.R.C.S.—a son.

SMITH.—On Dec. 10th, at Idrisyn, Hodford-road, Golders Green, the wife of A. Francis Smith, L.D.S., of a daughter.

DEATHS.

JARDINE.—On Dec. 7th, at Richmond, Surrey, James Jardine, M.B., C.M. Edin., in his 81st year.

NOEL-COX.—On Dec. 6th, at Clifton-gardens, W., Herbert Lovis Noel-Cox, M.D., F.R.A.S.

RISK.—On Dec. 7th, of heart failure, at Collingham-place, S.W., Colonel E. J. Erskine Risk, A.M.S. (retd.).

WARE.—On Dec. 5th, in London, Sydney Arthur Thomas Ware, M.B., B.S., of the Sudan Medical Service, aged 32 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

OCCUPATION AND HEALTH.

A FURTHER part of "Occupation and Health, an Encyclopædia of Hygiene, Pathology, and Social Welfare," published by the International Labour Office, Geneva, has just been issued. It contains brochures 36 to 45. This encyclopædia is being published in rather a novel way; each part contains such articles as are completed without waiting for the whole to be ready. Consecutive pagination finally will not be possible, but each article will be able to be arranged alphabetically for binding. The international character of this work is maintained in the present collection of brochures which are contributed by Dr. L. Carozzi (Geneva), Prof. A. Sclavo (Sienna), Prof. D. Ottolenghi (Bologna), and Dr. Brezina (Vienna). The article on anthrax is excellent and the statistics given show how the disease only occurs by infection from animals; in Great Britain the woollen industry has been the main source of cases with the handling of hides and skins second; in France hides and skins stand first, wool second; while in Germany hides and skins are first and wool is of little moment. Animal vaccination is well explained, and the early use of serum in all suspected cases is insisted upon; here the author, Prof. Sclavo, modestly says nothing of the part he has played in developing this line of treatment. The articles dealing with the soap industry, with picric acid, and with ammonia are good examples of accurate condensation. This publication is being issued simultaneously in French and English, and the translations, judging by the English text, are well done.

CALENDARS AND DIARIES FOR 1927.

A CONVENIENT block calendar for 1927 (the A.F.D. Diary) has been issued by the Anglo-French Drug Co (238A, Gray's Inn-road, London, W.C.). There is provided for each day throughout the year a sheet of white paper, 4 inches square, for written memoranda, and the stiff, hinged cover provided preserves the privacy of the notes and lends the calendar the appearance of a bound book. This year the cover is brown instead of black. A certain number are available gratis to medical men on application to the company.

A NEW JOURNAL OF ABSTRACTS.

THE *Revue Médicale* is a weekly journal in French, edited and published in Brussels, the purpose of which is to abstract the principal medical papers and books of all countries as soon as possible after they appear. Judging from Nos. 15 and 16, the matter selected for abstraction is mostly French and Belgian, but there is a sprinkling of German and English, and the scope will doubtless widen as the number of pages increases. The size of the review is about 6 in. by 9 in., and every page is perforated so that it may be easily removed for filing in a special index cabinet which the proprietors supply to subscribers. The price of this review is 40 francs a year, post free, and subscriptions may be sent to Compte chèque postal, *Revue Médicale* No. 413, 90, Brussels.

AN INFORMATIVE CATALOGUE.

THE second edition of Messrs. Ogilvy and Co.'s catalogue of microscopical illuminating apparatus should be of interest to pathologists who require standardised conditions of illumination for microscope work. The Hartridge-Williams axial illuminator, an entirely British production, is illustrated and described in detail and appears to combine all the essentials for constant and efficient lighting with a minimum of eyestrain. Axial illumination, by eliminating the variable factor of reflection, allows the observer to make any number of examinations under identical conditions. The Silverman illuminator for the microscopy of opaque surfaces, the K.B.B. lamp for work with monochromatic or ultra-violet light, and all the well-known forms of bench light are illustrated.

AN APPOINTMENT BOOK FOR DENTISTS.[1]

A HANDY appointment book, specially devised for dentists, is arranged for half-hourly appointments throughout the day. An indexed address book which slips into a pocket in the cover is a useful feature. The dangerous drugs register in the prescribed form, included as a separate booklet, is a timely reminder, in view of a recent prosecution, that dentists are affected by the legislation on this point. Most dentists keep cocaine in some form for local use, but many do not realise that all purchases of cocaine must be entered in a special book.

[1] Diary of Appointments, 1927, with Address Book. London Dental Manufacturing Co. 6*s*. 6*d*. Interleaved 8*s*. 6*d*.

THE COMPLETE WHITAKER.

Whitaker's Almanack for 1927 appears in two forms, of which the complete edition (pp. 896, green and red cloth, price 6*s*. as before) has been rearranged and contains some new features. Following the index is a convenient table of abbreviations in common use, including the various medical degrees and diplomas. Among the 57 short articles appearing under "Questions of the Day," towards the end of the volume, are handy summaries of the proposed factory legislation, of Sir George Newman's report to the Ministry of Health, and of the report of the Lunacy Commission. There is the customary paragraph on medical fees and charges, and a note—correct but all too brief—on the function of the General Medical Council, followed by a list of medical schools in London, with the names in each case of the medical secretary or dean. Under "English Counties and Shires" appears a scheduled list of sheriffs, clerks of the peace, and chief constables, in which the medical officer of health occupies the place of easy reference in the last column. Apart from definitely medical items, the whole book is pregnant with exact information indispensable to medical men whose work brings them into contact with public bodies and institutions. The index is so complete as to make cross-reference simple and easy. The abridged edition (pp. 240, paper cover, price 1*s*. 6*d*.) is a new book which contains as many index entries as any previous Almanack, but which has been shorn of details, although it still contains "Questions of the Day," the parliamentary summary, and the events of the preceding year. The Abridged Whitaker is small enough to be carried in the pocket.

ULSTER MEDICAL SOCIETY.

THE annual dinner of this society was held at Belfast on Dec. 9th, Dr. M. J. Nolan, the President, in the chair. Amongst the guests were the Duke of Abercorn (Governor of Northern Ireland), Sir William Turner (Lord Mayor of Belfast), Judge Thompson (Recorder of Belfast), Dr. R. W. Livingstone (Vice-Chancellor of Queen's University), Viscount Bangor, and Sir Frederick Moneypenny. After the loyal toast had been honoured, the President gave the toast of "His Grace the Governor, and Prosperity to Ireland," and the Duke of Abercorn responded. Mr. James A. Craig submitted the toast of "The City of Belfast," and the Lord Mayor responded. Dr. R. W. Leslie proposed "Our Guests," and the Recorder, the Vice-Chancellor of Queen's University, and Viscount Bangor responded. Mr. C. G. Crymble proposed the toast of the Royal College of Surgeons in Ireland, and Mr. Andrew Fullerton, who is a member of the Society, responded. Prof. J. A. Lindsay proposed the toast of The President, and Dr. Nolan responded. Subjects of importance referred to in the speeches included the need for a hostel for men students at the University, the deficiency in maternity accommodation in Belfast, and desirability of reform of the Lunacy Laws. The proceedings concluded with the singing of the National Anthem.

AN ANCIENT EGYPTIAN COSMETIC.

AMONG Mr. Howard Carter's finds in the tomb of Tut-Ankh-Amen at Luxor was a sealed calcite jar containing a cosmetic. The jar had been sealed naturally by the crystallisation of certain salts and had remained in a sterile atmosphere for more than 3000 years; when it was opened it was found to contain about a pound of fatty matter, of the colour of chocolate, and containing yellow nodules. It melted with the heat of the hand, and its smell was described by various observers as something like that of coconut, broom, or valerian. Mr. A. Chaston Chapman, F.R.S., and Mr. H. J. Plenderleith, of the British Museum Laboratory, communicated an account of its analysis to the *Journal of the Chemical Society* for October last. The results do not allow them to say what the fat was that formed 90 per cent. of the whole, but since the chemical evidence excluded coconut or palm-kernel oils, and it is improbable that any vegetable fat with such a small amount of olein as this specimen contained would have been available, it was probably animal fat. The remaining 10 per cent. was composed of some resin or balsam. The smell was probably one of the results of oxidation in this resin, as the odoriferous constituents of coconut are, as far as is known, not stable enough to survive the action of oxygen and moisture over so long a period.

ROYAL SOCIETY OF MEDICINE.—The Society's house and library will be closed from Thursday, Dec. 23rd, to Tuesday, Dec. 28th, both days inclusive.

UNIVERSITY OF SYDNEY.—The Agent-General for New South Wales announces that Dr. W. S. Dawson, of the Maudsley Hospital (London County Council), has been appointed professor of psychiatry. Mr. Horace Finnemore, B.Sc., of Guy's Hospital Medical School, has been appointed lecturer in pharmacy.

Some Notes ON ADOLESCENT ALBUMINURIA: INCIDENCE, SIGNIFICANCE, AND AFTER-HISTORY.

BY H. H. BASHFORD, M.D., B.S. LOND.,
ASSISTANT MEDICAL OFFICER, GENERAL POST OFFICE.

THERE is now a very general recognition that the mere presence of albumin in the urine of adolescents and young adults need not be regarded so gravely as was once the case, provided that it is unaccompanied by any other signs of renal or constitutional disability.

At the time, however, that the present investigation was begun, in 1909, this condition was still looked upon with much suspicion, and was in itself sufficient to debar many otherwise healthy-seeming candidates from various pensionable services, including the Army and Navy, while most insurance societies "loaded" such applicants, if they did not refuse them altogether. Since then a considerable amount of work has been done on the subject, particularly amongst schoolboys, army recruits, and athletes; and the regular occurrence, during systematic series of examinations, of apparently healthy individuals, whose urine, especially after exercise, contains albumin, has led to the prima facie assumption that it cannot be of very serious import. Various theories have also been advanced as to the probable cause of the phenomenon, which has been stated to be associated chiefly with boys and youths of a weedy, neurotic type; to be due to vasomotor instability, as evidenced in a history of faints on parade, in church, and so on; to be the result of pressure on renal vessels by lordosis; to be due to irritation caused by oxalate crystals; and, more recently, to betoken an unnoticed or mis-diagnosed attack of scarlet fever.

With its exact histological or physiological explanation I have not been concerned in the following inquiry—I am only aware, though probably others have been recorded, of one case in which post-mortem attention was paid to the fact, the patient dying from a glioma and the kidneys being found healthy—but these various theories have been borne in mind during the investigation, which has been chiefly directed to obtaining some idea of its exact incidence, its persistence or otherwise in later life, and its significance in respect of general physical efficiency.

INCIDENCE.

With regard to its incidence, in a consecutive series of 1000 examinations of boys of 14 years of age, examined by the Headquarters Medical Department of the General Post Office between July, 1924, and April, 1926, 58 were found to have albumin in their urine. Of these 58 boys the lightest weighed just 5 st. and the heaviest exactly 10 st. In one case there was found an associated mitral lesion. But the others, who were of every type and build, were found to be organically sound and healthy, although 14 of them were unsuitable for the particular purpose for which they were being examined on account of minor defects, such as flat-feet or defective vision. The urine of these 14 boys was not again examined. But of the remaining 43, albumin was found to be absent from the morning or after-rest specimen in 40 of them.

In a second group of 500 consecutive cases of males between the ages of 14 and 30, examined in all parts of England, but referred to headquarters on account of some abnormality found, albuminuria, without any apparent organic disease, was present in 41 of them. Five of these cases were of men over 25, and in only 3 of the 41 cases was there a previous history of scarlet fever. Of these 41 cases, further examination showed the albumin to have disappeared from the morning or after-rest specimen in 30 of them.

RELATION TO PHYSICAL EFFICIENCY AND SICK RECORD IN LATER LIFE.

The main object, however, of the present investigation has been to trace the effect, if any, in after life of this variously called functional, postural, or adolescent albuminuria upon the physical efficiency and sick record of the individuals concerned. To have been able to do so, I am primarily indebted to the late chief medical officer of the General Post Office, Dr. John Sinclair, C.B.E., and his predecessor, Dr. A. H. Wilson. Both these observers, after a very wide experience amongst adolescents and young adults, had for some years, and to a certain extent in advance of general contemporary medical opinion, came to the conclusion that the condition was not such as should, in itself, debar candidates from acceptance on medical grounds. By the year 1909, therefore, when this inquiry was begun, there was a considerable number of such cases at hand, and having traced the first consecutive 30, of which the records were available, I was enabled to re-examine them after periods of service varying from seven to 14 years. All of them were men without exception in good health, their sick records being mostly of a trivial nature. None of them exhibited the lordosis that had been put forward as a possible explanation of the condition. Only five of them were marked down as being of a nervous type. Only two of them remembered fainting. There was a history of scarlet fever in only one case. And in only one case were oxalates found to any noticeable extent. With regard to the condition itself, I found albumin still present in the urine of six out of the 30, the morning or after-rest specimen being clear in five out of these six cases. It is interesting to note that this latter case died seven years later with acute nephritis, whether as a last stage of a gradual process indicated by the albuminuria found—it was discovered at the age of 19 and he died at 35—or whether, in legal phraseology, as a *novus actus interveniens*, I am not prepared to say, though I suspect the latter.

With the exception of this case and five others, I have been able to examine the whole group again in 1926—i.e., another 17 years later—and possibly the following table of results may be of some general interest.

From the table it will be seen that of the six cases I have been unable to re-examine a second time, in two instances it has been due to the fact that I have been unable, for various reasons, to trace them. Of the remaining four, reference has been made to one, and the other three left the service, one with cyclitis and eye trouble, one as the result of acquired syphilis, and one as the result of a gastric ulcer. In none of these cases, I think, can there be any legitimate inference that their albuminuria had anything to do with it. Of the remaining 24, all are in good average health, and most of them with good sick records, while such illnesses as they have had have no apparent association with renal causes, No. 19 being the only possible exception. It will be seen that in the second re-examination the condition was found to be persisting in only one of the group—namely, in a member who was free on the previous re-examination, his morning or after-rest specimen containing no albumin.

With regard to this latter point, it is certainly the case, almost to the point, perhaps, of being characteristic of the condition, that albumin is usually absent from the urine after a period of sleep or the usual night's rest. And this morning freedom is very generally, from the point of view of medical policy in advising upon such cases, taken to be a rough practical guide; and cases in which albumin is consistently found in the after-rest specimen ought certainly, in my opinion, to be regarded more stringently.

Again, as regards the persistence of the condition into later life, the above group shows a marked diminution as life goes on. But I have a strong suspicion that, were it practicable to make rather more regular and frequent examinations, the persistence of

adolescent albuminuria would be found to be a good deal more common than is supposed, and to be the real explanation of a good many middle-aged albuminurics. In this connexion the following case, typical of several, which have also come under my notice, may be of some interest :—

P. H., a journalist and traveller, was discovered to have albuminuria at the age of 18, and, though he appeared to be otherwise healthy, was ordered by one or two specialists at the time to avoid hard exercise and undertake various modifications of diet, &c. Later, being an athlete, and feeling perfectly well, he grew tired of these restrictions, resumed his usual avocations, including Rugby football, at which he attained county status, and has since been, and is now, at the age of 46, an exceptionally healthy and active man, who has scarcely had a day's illness in his life. Periodical examinations have, however, for the last 28 years, almost invariably shown very large traces of albumin in his daily urine, though never in the after-rest specimen.

CONCLUSION.

In conclusion, I think it may be stated : 1. That about one in every 20 young male adolescents will be found to exhibit the condition. 2. That in a considerable number of instances the condition persists for many years, if not throughout life. 3. That its presence is consistent with the prospects of a perfectly normal life of physical efficiency. 4. That in the great majority of cases the after-rest specimen is usually free from albumin. 5. That it is not definitely associated with any particular type of youth or man, with a so-called " nervous " disposition, with lordosis, oxaluria, or a history of scarlet fever.

Finally, as a point of incidental interest, and perhaps for further investigation, the above group of adolescent albuminurics have produced between them 14 sons who have attained puberty, two of whom present the same condition as their fathers. The figures are too small for deductions. But the proportion is certainly, as it stands, markedly higher than the average.

I am indebted to the Chief Medical Officer of the General Post Office, Colonel H. V. Prynne, C.B.E., D.S.O., and to the Secretary for permission to publish the relative figures, and to Mr. F. G. Lamb, of the medical department, and the staff officers of the various sick absence duties in the Post Office for their kindly assistance.

PROGNOSIS IN RECTAL CANCER.*

BY J. P. LOCKHART-MUMMERY, F.R.C.S.ENG.,
SENIOR SURGEON TO ST. MARK'S HOSPITAL FOR DISEASES OF THE RECTUM.

THIS is a most difficult subject, since there are so very many factors which affect the estimate we may make in any individual case, and it is obvious that only a very approximate estimate can be arrived at. The improvements in the treatment of rectal carcinoma during recent years have been very considerable, and it is very important that those who have to deal with such cases should have their knowledge brought up to date as to the possibilities of what can be achieved by the various methods of treatment in these very distressing cases.

The word " prognosis " does not lend itself to very easy definition. It means, I take it, a prophecy as to the future history of the patient ; more particularly what chances there are of the patient being cured of the disease from which he suffers, and what his chances of survival are without any treatment.

Factors in Prognosis.

There are three factors which have the very greatest importance in estimating prognosis. These are : age of the patient, the stage of the disease when first seen, and the position of the growth.

To deal first of all with the question of age. There is no doubt that carcinoma behaves very differently at different periods of life. In young people the tendency is for the disease to grow extremely rapidly and at an early age to spread to other tissues. One may say that in such patients the disease has a tendency to fulminate, whereas at the opposite end of life we find the disease extremely chronic and growing very slowly. I have seen patients as young as 8 with cancer of the rectum, but, fortunately, the disease is rare under the age of 40.

The prognosis as regards cure of a patient under 30 years of age suffering from cancer of the rectum is extremely bad ; in fact, I have no record of any patient treated for cancer of the rectum under 30 who has not died from prompt recurrence, no matter how drastic the operation, or other treatment, had been. I doubt, in fact, whether it is worth while operating at all on patients under 30 for cancer of the rectum. On the other hand, very old patients, say of 80 or more, may have a carcinoma for many years which grows so extremely slowly that it is doubtful whether it is worth while operating on it, even if this is possible. I know of one patient, now 85 years of age, who has had an epithelioma of the anus for 25 years, and to all intents and purposes the disease is behaving like a wart, although there is no doubt of the diagnosis, a microscopical examination of specimens having been made on three different occasions. It is thus obvious that age is a very important factor in estimating prognosis.

To turn now to the stage of the disease when first seen. This is probably the most important factor of all, and it is here that we have the greatest chance of improving our present statistics, as I shall be able to show presently. That is to say, that if the disease is diagnosed early and has not invaded surrounding tissues, the prognosis with operation is good, and gets progressively worse as the disease is found to have advanced.

Thirdly, we have the position of the growth. There are three main positions. An epithelioma of the anus, an adenocarcinoma of the rectum itself, and an adenocarcinoma of the rectosigmoidal junction. In a case of epithelioma the prognosis is good provided the diagnosis is made early. Fortunately this is usually the case, owing to the fact that the growth quickly draws attention to itself and can easily be seen. Growths in the rectum also have a good prognosis, provided they are detected early and suitably operated on. Growths at the rectosigmoidal junction have not such a good prognosis as in cases of the growths of the rectum. The reason for this is that they can only be removed by a much more serious operation, and that it is more difficult to remove the secondary glands and tissues in immediate contact with the growth. In other words, the growth cannot be so completely or satisfactorily removed as in cases of cancer of the rectum. Another factor that renders the prognosis less favourable is that such growths are less frequently detected until a late stage of the disease owing to the fact that they cannot be felt with the finger.

Prognosis in an Untreated Case.

Before we consider the results of treatment it may be as well to consider what the prognosis is in an untreated case. It is only by comparing the results of untreated cases with those that are treated that we can get a satisfactory idea of the amount of benefit that the treatment confers upon the patient.

The only really satisfactory figures bearing on this subject are those published by Prof. W. S. Lazarus-Barlow and Dr. J. H. Leeming.[1] These figures purport to show the natural duration of cancer at different ages taken from a large number of figures. The duration for cancer of the rectum at the commonest decennial period, which is 55–64, shows a mean duration of 21 months, which is a little under two years. Roughly, therefore, we may say that a patient with cancer of the rectum who is only treated on symptomatic lines

* Paper read at the Post-Graduate Hostel.

[1] Brit. Med. Jour., August 16th, 1924.

has a little under two years to live, calculated on the average of a large number of cases. There are, of course, extremes. Some growths may cause the death of a patient within a few months, while other patients may live for many years. Apart from the case already quoted of epithelioma of the anus, I know of one case where a patient with carcinoma of the rectum which was not operated upon remained in comparatively good health for seven years. Such cases are, however, rare.

Prognosis in Operated Cases.

To turn now to the prognosis in operated cases. I shall deal first with epithelioma of the anus and adenocarcinoma of the rectum proper. There is still rather a general belief that the prognosis in such cases is bad, and that although a few patients may be benefited by operation the majority die from early recurrence in spite of operation. I hope to show that this very pessimistic view is not justified in the light of modern statistics.

Cases of epithelioma and cancer of the rectum can, in these days, best be dealt with by what is known as the perineal operation with a permanent colostomy, and I propose first of all to give you these figures to show what may be achieved by this method of treatment. I have just recently completed a sequence of 200 cases operated upon by this method. These do not include cases of carcinoma of the recto-sigmoidal junction which have been dealt with by the abdominoperineal excision. The period covered by the series is, naturally, a long one, and although the mortality figures are calculated upon the whole 200 cases, the recurrence figures are only worked out upon those cases which were done more than five years ago, since the more recent ones are obviously not available. In discussing the prognosis we have to take into account the operative mortality, and I am glad to say that at last we have been able to reduce the operative risk in cases of cancer of the rectum to quite satisfactory figures. In my last 100 private cases there were only three deaths, which gives a 3 per cent. mortality. This, considering that we have to deal with patients up to about 76 years of age, often with concurrent disease, is probably as low as can be hoped for. The 100 hospital cases do not show quite such a low mortality. This is largely due to the fact that cases come up for treatment much later and that their general condition is not nearly so good as in the case of the richer classes. It is now my custom to keep all hospital patients at least a week in bed before any operation is performed, and this has already considerably reduced the mortality risk.

I have always maintained that no operation for cancer of the rectum is satisfactory unless it can deal with cases which from the surgeon's point of view are bad risks, as it is inevitable that in dealing with a disease like cancer many of the patients must be advanced in age and have other associated diseases. Thus in my 200 cases 72 patients were over the age of 60 and 14 over the age of 70. As regards associated disease, three patients had diabetes two Graves's, disease, one Hodgkin's disease, three diverticulitis, one woman had an aortic aneurysm, and one man had hæmophilia. Naturally every possible precaution was taken to get the patient into as good condition as possible before operation in these cases of associated disease. The diabetics were treated with insulin, and in all cases the anæsthetic of choice was gas and oxygen and spinal, or twilight sleep and local anæsthesia.

We may see, therefore, that as regards the mortality risk from cancer of the rectum where the case can be dealt with by a perineal resection the risk is not more than about 3 per cent. This figure, of course, is only arrived at by very careful management, the most important factors being the anæsthetic, designed so as to produce a shockless operation, doing the operation in two stages, the colostomy a week or ten days before the excision, and careful team-work on the part of everybody concerned. Both I and my assistant and nurses have had considerable experience with these cases, and it is only by great care that we have been able to get the mortality figure as low as 3 per cent.

The chief cause of mortality used to be sepsis. By careful technique this has been practically eliminated, and the main causes of mortality at the present time are post-operative infarct and heart failure. Pneumonia also accounted for two of the deaths in the hospital cases, and is a complication which is practically unavoidable in this climate where one has to deal with elderly patients who have to be kept in a recumbent position for some time.

In the case of growths at the rectosigmoidal junction which have to be dealt with by abdomino-perineal resection we have not been so successful in reducing the mortality. Considerable improvement has occurred, but it is doubtful whether with so serious an operation the mortality can be kept much below 25 per cent., and that only by eliminating a good many bad risks that would be easily dealt with by the perineal method. The operation is a much more severe one, and involves considerable interference with the abdominal cavity. Hence its much higher mortality.

Recurrence.

The most important factor in arriving at a satisfactory prognosis is the proportion of recurrences. Most surgeons have worked out recurrence rates on a three-year basis, but it has always been my opinion that this period is far too short, as cases that are not operated on at all not infrequently survive a three-year period. A five-year period is much more satisfactory, though still open to the objection that recurrence may occur after five years. The enormous difficulty in keeping in touch with a large number of patients over periods greater than five years, and the fact that a considerable number will die of other causes, renders it impossible to take anything more than a five-year period. The following figures, therefore, have been worked out on this basis.

There were in all 95 cases operated on five years ago or over. These work out as follows :—

Cures on a five-year basis	45
Recurrences	37
Died from other causes	6
Untraced	7
Total	95

If we subtract the untraced cases and those that died from other causes it gives us a percentage of cures of 54·8. If instead of subtracting these cases we divide them into their probable recurrence rate, which on the average of the remaining cases would be about 50 per cent., we get a percentage cure of 53·6. It seems probable from these figures that we can, therefore, disregard the cases that died from other causes or that are untraced.

If we take a three-year basis instead of a five-year there are 125 cases with cures, 73; recurrences, 42; or a percentage cure of 55·5.

If we examine the figures in a little more detail several interesting points emerge. All the cases were originally divided into three classes: (A) very favourable cases where the growth was small and had not invaded the muscular coat and no glands were involved; (B) cases where the muscular coat was involved, but where the growth was not unduly fixed and there was not extensive involvement of glands; (C) bad borderline cases, with a large, fixed growth and evidence of extensive involvement of glands. Out of a total of 200 cases 73 were A cases, 96 were B cases, and 31 were C cases. An analysis of these three classes as regards recurrence shows very interesting results. The percentage of cures in the A cases on a five-year basis was 73·7, in the B cases 44·8, and in the C cases 44·4. This shows that with favourable cases where the growth is operated upon at an early stage the chances of permanent cure on a five-year basis is nearly 3 to 1. The figures in the C cases are, doubtless, misleading, since they are probably too few, but one very important point is demonstrated—namely

that such cases are well worth operating upon. Most of these cases were so bad that it was doubtful whether operation was advisable, and yet 44 per cent. survived a five-year period after operation, and one was alive over 18 years later.

I have made an attempt to trace the after-history of 39 of the cases who survived the five-year period, and the annexed table shows what happened to these patients :—

Table of 39 Cases Traced Beyond 5 Years showing the Number of Years that have Elapsed Since Operation.

Cases.	Years.	Cases.	Years.	Cases.	Years.
1	21	3	10	8	7
2	14	3	9	13	6
2	11	7	8		

Disability Produced by Operation.

When dealing with so serious and fatal a disease as cancer, disability after operation is a relatively unimportant factor. It becomes important, however, when comparing one method of treatment with another.

The disability which results from the perineal operation is entirely due to the presence of a permanent colostomy opening in place of the normal anus. This is, of course, also true of the abdomino-perineal operation. This disability is not a serious one—in fact, not nearly so serious as might well be imagined. Patients are able to live comfortable and useful lives, and after the first few months it is remarkable how little inconvenience the colostomy causes.

The best way, perhaps, to estimate the disability is in reference to the wage-earning capacity of hospital patients. We find that this is not diminished except in the case of very heavy labour involving strenuous exertion. The vast majority of patients were found to have been in the same employment as formerly. Thus out of 20 cases apparently cured by operation, six were women, five of whom did their housework, and one was a stationmaster's assistant. There were 14 men, of whom ten were in full work in the following occupations : printer's cutter, fish-curer, schoolmaster, packer, tailor, pilot, messenger, waiter, platelayer, and odd-job man. Three were living in retirement, being over 65 years of age, and one, who used to be a farm labourer, no longer works.

The figures show that when an operation is performed for cancer of the rectum under the most favourable conditions and the growth is diagnosed at an early stage, the prognosis as regards cure is good. The mortality is only 3 per cent. and the percentage of cures on a five-year basis in early growths is 73 per cent., while with the average of cases as they present themselves it is over 50 per cent. These results are, of course, only obtained by considerable experience in operations on the rectum and where the case is handled to a large extent by team-work.

Other Methods of Treatment.

As regards treatment by *deep X rays*. I cannot say that I have seen any cures from this method. Doses of X rays sufficiently powerful to destroy a growth in the rectum are decidedly dangerous, and I have seen one death from the rays. It has always seemed to me that there is a decided danger of stimulating parts of the growth which have not received a lethal dose to greater activity. At least I have thought that cases treated by rays in some instances died from extensive secondary growths more rapidly than I should have expected. At one time I was using X rays after operation as a means of preventing recurrence, but for some years now I have discontinued doing so. I have in a few cases seen good results from X rays in the treatment of epithelioma, and one case I believe to have been cured by this means. My opinion is that deep X rays as a means of curing cancer of the rectum are a failure.

With regard to *radium*. I know of no cure of a case of cancer of the rectum from the use of radium. The old method of applying radium tubes to the growth by means of applicators passed through a speculum into the bowel and retained there by means of a wire has proved quite useless, and, at any rate in my own practice, has been discarded. A much better method is that which I am now using of inserting radium needles into the base of the growth itself. The needles contain 10 mg. of radium bromide, or its equivalent in emanation, and from 10 to 12 needles are inserted for 24–36 hours. The actual method, of course, varies with the case to be treated. Roughly, it is as follows. An incision is made under an anæsthetic through the skin to enable the base of the growth to be reached without going through the rectal wall. If the growth is on the posterior wall the coccyx may be removed. The needles, with silk threads attached to them, are then passed by means of a special instrument deep into the base of the growth. The ideal arrangement is to have the needles in a fan shape with their points well beyond the limits of the growth and about ½ inch apart, so that the whole upper crescent of the growth will be affected. The threads are left hanging out and the wound stitched up. Next day—i.e., in 24–36 hours—the wound is opened and the radium needles removed, and the wound again closed. Naturally, great care is taken to avoid sepsis. To be effective the treatment should be repeated in from 4–6 weeks, the lower half of the growth being then similarly treated. I have not as yet had sufficient experience of the treatment to give you any results. I can only say that so far as they go the results appear to be much better than any that were secured by the old method. There does not seem to be any severe reaction, such as was often experienced formerly.

Colloidal Copper.—This treatment undoubtedly does good, and my experience of it must run now to over 200 cases. I have seen two cases which were apparently cured by this means. I say apparently because although in both an undoubted carcinoma of the rectum entirely disappeared after some 8–9 months of continuous treatment with colloidal copper, one cannot be sure when the proportion of cures is so small that the cure was due to the copper and not to some other fortuitous circumstance. Apart from these two cases I am quite certain that the treatment does a lot of good. I am convinced that it delays the growth of the tumour and reduces the secondary ulceration. It seems to act by tending to fibrose the growth. In practice it tends to prolong the patient's life and to increase his comfort and well-being. There is, so far as I know, no danger from the treatment.

The treatment with *Colloidal Lead* is on a different footing, as a considerably greater proportion of cures is claimed for this method of treatment. The lead acts by poisoning the tumour cells and so destroying their reproductive properties. This treatment is at present still in the experimental stage, but the results are very encouraging. Unfortunately, there is considerable danger attending the use of colloidal lead, both from the rapid reaction of the tumour itself and from acute plumbism from the direct effects of lead in the circulation.

SHROPSHIRE ORTHOPÆDIC HOSPITAL.—On Friday in last week the ex-King of Portugal opened a new ward at this hospital at Gobowen, near Oswestry.

INSURED PATIENTS IN HOSPITALS.—The Committee of Queen Mary's Hospital for the East End has asked the British Hospitals' Association to consider "the matter of charges in connexion with casualties where injured persons receive sums of money in compensation, so as to enable hospitals to recover their costs, and put a stop to insurance companies and private individuals gaining a profit at the expense of the hospitals." It is pointed out that although one insurance company has endowed a bed at different hospitals, most of the others fail to recognise responsibility when their insured are hurt. It is added that when injured persons in county court actions present an account of hospital costs the judges almost invariably refuse to take these costs into consideration on the ground that no fees are asked from patients.

CLOSED RENAL TUBERCULOSIS.

WITH A REPORT ON FIVE CASES.

BY H. P. WINSBURY WHITE, F.R.C.S. ENG.,
HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS, ENGLAND, 1925; ASSISTANT SURGEON, ST. PAUL'S HOSPITAL FOR GENITO-URINARY DISEASES.

THE term closed is applied to those cases in which the tuberculous disease in the kidney is shut off from the rest of the urinary tract. The closure may occur by the encapsulation of a small focus in the kidney itself, or by the sealing-off of a calyx, the renal pelvis, or the ureter. It most commonly results from a combination of the last two processes.

The facts which have given special importance to this product of renal tuberculosis are, first of all, that the occlusion may result in the cure of the urinary tuberculosis, and, secondly, that the disease can develop and reach the stage of complete functional obliteration of the kidney before the presence of any disease of the urinary apparatus is suspected by the patient. Personal contact for the first time with such facts is likely to come as a surprise to the surgeon who rightly associates marked disturbances of micturition with renal tuberculosis, for more than 90 per cent. of cases give rise to dysuria and frequency.[1]

The condition first received prominence less than 40 years ago, when several cases were published within a short time.[2] In those days, however, as cystoscopy was only in its infancy, the diagnosis was often only made certain on the post-mortem table. In 1906 the most valuable contribution which has ever been published, dealing with the pathological anatomy of the condition, appeared under the combined authorship of Hallé and Motz.[3] These writers established its comparative frequence by finding that complete occlusion of the ureter occurred in 18 examples of the 100 specimens of renal tuberculosis which they investigated at the Musée de Necker. In the following year the subject was widely discussed at the congress of German urologists, when Zuckerkandl[4] introduced the descriptive designation of Pyonephrosis Tuberculosa Occlusa. Up to 1913 only a few cases had been reported, for Smirnow[5] at this time was only able to collect 24 from the literature.

Incidence.

Even up to the present day this form of renal tuberculosis is generally referred to as rare. The figures of Hallé and Motz, however, show that it is quite the reverse; while Braasch, in reviewing 621 cases which were operated upon for tuberculosis of the kidney at the Mayo clinic between 1900 and 1919, reports that renal occlusion occurs in about 10 per cent. of the cases of chronic renal tuberculosis. Finally, my own personal experience of five cases within a period of three years adds a less important but, nevertheless, an emphatic support to the view that the condition is not at all uncommon.

Age.—As renal tuberculosis has its most frequent incidence between the ages of 20 and 30 years, it is not surprising that occlusion, which represents a final stage of the disease, is found most commonly at a later period—namely, during the fourth and fifth decades. Cabot and Crabtree,[6] in reviewing 70 cases of renal tuberculosis, state that all their cases over 50 years, four in number, were represented by a calcareous kidney with autonephrectomy. It is by no means confined to the later periods of life, however, for two of my own cases were discovered at the ages of 19 and 20, while a number of those reported in the literature were also young adults.[7]

It must not be forgotten that renal tuberculosis in children, although often accompanied by tuberculosis in other parts of the body, is not infrequent. Barthez and Rilliat,[8] in 72 autopsies on children under 12 with active tuberculosis, found renal lesions due to the tubercle bacillus in 68 per cent. In adult cases, from whom no history of any urinary disturbance can be elicited, it is not possible to know at what age the disease commenced.

Because urinary tuberculosis is more common in men than in women, on account of the greater incidence of genital tuberculosis in the male sex, there is a corresponding predominance of closed renal tuberculosis in men. There is no greater incidence of the condition in one kidney than in the other.

Pathology.

In order to obtain a clear idea of the way in which the ureter may become occluded, it is necessary to consider the changes which take place in this structure as the disease in the kidney progresses. The ureter only shows tuberculous lesions as a result of similar lesions in the kidney above, for there is a complete lack of anatomical evidence that the ureter can be infected by an upward spread along its lumen from the bladder, and one has yet to hear of a specimen showing tuberculous lesions of the bladder and of one of the ureters with the corresponding kidney free from infection with the bacillus of Koch.

With the disease established in the kidney above, the main excretory duct and its tributaries soon become the seat of tuberculous lesions, simply as a result of contact of the bacilli in the urine with the lining mucosa. Discrete tubercles first form in the submucosa; these quickly give rise to superficial ulcers, which become confluent and may involve the whole tube in a superficial ulceration. The calyces and the pelvis generally suffer first, frequently the extra-vesical portion of the ureter is next, while the intervening portion becomes involved later; but this sequence is by no means constant.

The factors which determine the first and the last of the foregoing situations as the likely sites of the early lesions are: first, that there is a physiological delay of the urine in the renal pelvis and in the extra-vesical portion of the ureter; and, secondly, the rudimentary type of epithelium in the calyco-papillary angle offers an easy path of entry for the bacillus, and explains the readiness with which the infection at the upper end of the tract commences in this situation. In 100 specimens Hallé and Motz found the whole length of the ureter from kidney to bladder involved in 70, while in the remaining 30 the lesions were localised to either the vesical end or to the pelvis.

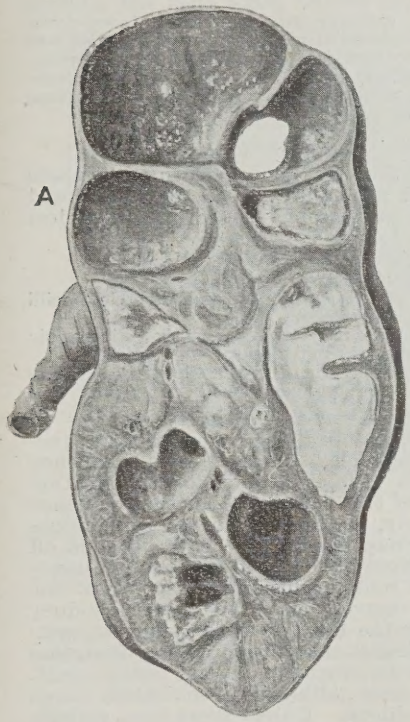
Infection of the bladder results from direct extension of the ulceration from the ureteric orifice, or this latter structure may be quite free, and the bladder may become infected by direct contact with tubercle bacilli carried in the urine from some focus higher up in the urinary tract. The bladder may, indeed, be free from infection altogether, and if the lower end of the ureter has also escaped, we have an explanation of those cases which remain without vesical symptoms throughout their course, even to the extent of complete destruction of the kidney. As a result of any chronic inflammatory process in the kidney, quite independently of tuberculous infection, the ureter undergoes a series of changes. First of all, this structure is dilated throughout its whole length, to be followed soon by thickening of the ureteral wall, resulting from a deposition of fibrous tissue in the mucous and submucous zones.

These phenomena of dilatation and thickening of the ureter are commonly seen as a result of *Bacillus coli* pyelitis and the chronic pyelitis which is generally seen with stone in the renal pelvis (see Fig. 1). The fibrous tissue in the wall of the ureter ultimately begins to contract so that, finally, dilatation may be replaced by stenosis. There is an essential difference between the stenosis which occurs in non-tuberculous and in tuberculous inflammation. In the latter the narrowing tends to be much more severe, on account of the actual ulceration which is present in the condition. It is this factor which, in giving rise to the destruction of the mucous membrane, causes the lumen to be finally occupied by scar tissue, and thus to be completely obliterated.

Once the tuberculous process has settled in the kidney, this organ will be eventually completely destroyed by the chronic ulceration, unless either death intervenes or the kidney is removed by surgical operation (see Fig. 1 C). For although cases have from time to time been reported with clinical data suggesting a cure, yet no specimen has ever been brought forward demonstrating that renal tuberculosis is capable of healing, short of complete destruction of the renal organ.

Three Specimens of Tuberculous Kidneys illustrating the Three Stages of Chronic Inflammatory Change in the Ureter.

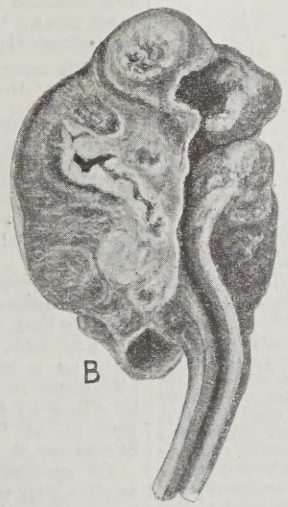
FIG. 1 A.—*Dilatation.*



(*Figs. 1 A and 1 B from the Museum of the Royal Free Hospital.*)

While the process continues in the kidney, provided there is no obstruction to the escape of the products of the necrosis down the ureter, so the ulceration in the walls of the latter structure will extend more and more deeply, until, ultimately, the whole mucosa and musculature may completely disappear. If such a stage is reached, the ureter consists of a rigid fibrous tissue tube of a diameter considerably beyond that of a normal ureter, and often strictured in places. This new formation develops in the periureteral zone in response to the peripherally spreading inflammation, so that the ureter itself has actually disappeared in spite of the presence of what appears to be an enlarged example of this structure. All operators experienced in urinary surgery are familiar with this type of ureter. If the disease in the kidney proceeds to the stage of complete destruction of all excreting renal tissue, localised and finally generalised contraction with obliteration of the ureteral lumen will be the result. At any time before this stage is reached the end of the kidney may be hastened by the blockage with caseous material of the pelvis, or the partly obstructed ureter; but what is least expected is that the occlusion is not dependent on deep and extensive ulceration of the ureteral wall. In the large majority the blockage occurs while the stage of ulceration in the ureter is still early; often with the greater part of the musculature yet intact, and with periureteritis slight or entirely absent. Hallé and Motz found this condition in 15 out of 18 examples of renal occlusion. The following is an abstract of their findings:—

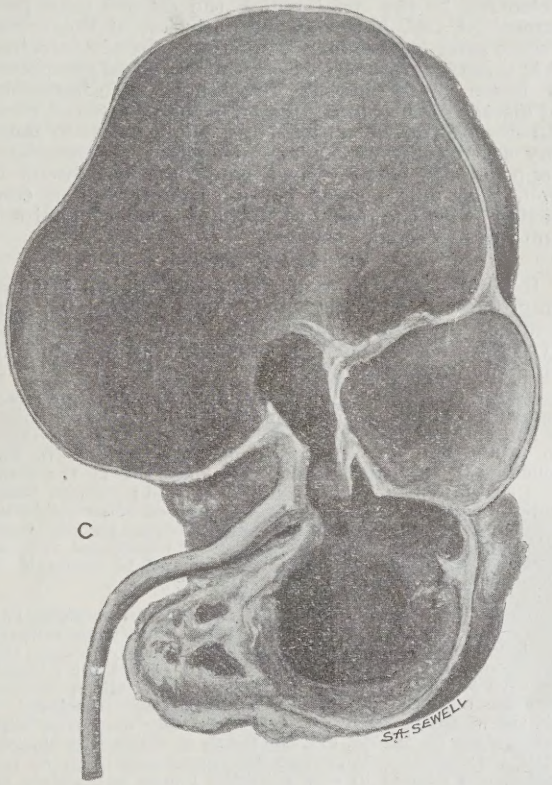
FIG. 1 B.—*Thickening.*



The ureter is only slightly, and often not at all, increased in size; sometimes it is even smaller than normal in the form of a solid cord. Its outer surface is consistently regular without periureteritis or excess of fat.

As a rule, this description applies to the ureter throughout its whole length, and the occlusion also involves the whole length of the tube. Sometimes a segment of varying length is alone obliterated and reduced to a solid cord, while, above and below, one finds the commonplace changes of tuberculous ureteritis. Both on naked eye and microscopic examination no lumen is discernible, as this is replaced by fibrous tissue, while a complete muscular coat with well-marked bundles is usually seen.

FIG. 1 C.—*Contraction.*



It is an obstruction to the outlet from the pelvis which seems to determine the healing and occlusion of the ureter, for the latter change is accompanied almost constantly by the obliteration of the pelvis and calyces. Hallé and Motz found this to be the case in all their specimens. In each of my own cases the lumen of the pelvis could be seen to be obliterated in one by caseous material; in another (Fig. 3) by scar tissue; and in a third by calcified caseous material.

It is this complete obstruction to the pelvic outlet which at one and the same time determines the rapid disintegration of all remaining renal tissue, if any still exists, while it provides circumstances favourable for the healing of the ureter by suppressing its conducting function and by cutting off the supply of further organisms from above. Evidence that the former plays a part is supplied by the knowledge that occlusion of the ureter down to its very orifice ultimately occurs after nephrectomy for kidney disease, other than tuberculosis, such as primary hydronephrosis. That the cutting-off of the supply of bacilli to the ureteral mucosa institutes the healing process in the ureter, as in the bladder, is borne out by the results of one's operative experience in dividing a tuberculous ureter in doing a nephrectomy, when, although it is obvious that the portion of ureter left behind is

tuberculous, yet the lumbar wound heals by first intention, while the vesical symptoms of the disease disappear.

Symptoms.

It must be clear that if the pelvic obstruction occurs while the ureteral ulceration is still in an early stage, and while no vesical ulceration has yet occurred, there is a considerable probability that no bladder symptoms have resulted either, and that the disease will now progress to its final stage without these arising; and unless there are features directing attention to the renal region the disease may pass unnoticed. If, however, the occlusion of the ureter occurs after the bladder has become already infected, it is usual in a unilateral case for the vesical symptoms to lessen, or to clear up altogether. Manifestations of disease in the kidney region in many cases of renal tuberculosis may be absent, or so slight as not to cause any serious attention; and, therefore, it sometimes happens that when vesical symptoms are absent as well, that unless some complication arises in connexion with the kidney, the real state of affairs is quite unsuspected.

Clinical Records.

It is important to realise that the clinical features may vary considerably in different patients; for instance, my own experience, which amounts to five cases, resulted in each one manifesting itself in a different way, as follows:—

CASE 1.—A policeman, aged 40, who was killed in a street accident. At the post-mortem examination there was found a left tuberculous pyonephrosis with the ureter reduced to a fibrous cord. On examining the bladder it was found that the left ureteric orifice had shared the same fate as the lumen, as it no longer existed; its site being indicated by a mere dimple on the mucosa of an otherwise perfectly healthy bladder. The widow stated that, although she had been married to the deceased for ten years, she had never known her husband to complain of either urinary trouble or pain in the left side.

CASE 2.—A female, aged 40, who for the previous two years had complained of pain in the epigastrium towards the left side. The urine showed no pathological elements, and cystoscopy revealed a healthy bladder except for a small inactive left ureteric orifice which would admit a ureteric catheter only for 3 cm. Left nephrectomy disclosed a kidney whose parenchyma was completely destroyed with tuberculous ulceration, and the pelvis of which was blocked with caseous material, while the uppermost inch of the ureter was normal in size with the lumen not visible on naked-eye examination, and without any periureteral adhesions. The microscope made it clear that this portion of the ureter still retained a considerable proportion of muscle in its walls, which, however, were occupied largely by fibrous tissue, resulting in great shrinkage of the lumen which was occupied by caseous material (Fig. 2).

CASE 3.—A female, aged 28, who had suffered from frequency of micturition with dysuria for 12 years. On cystoscopy a typical golf-hole left ureter which admitted a catheter for 30 cm. and discharged turbid urine. The right ureteric orifice was very obvious and accessible to a catheter, but this could not be made to enter, as epithelium had grown across and sealed the opening. Guinea-pig inoculation with the deposit of the bladder urine gave a positive result for tubercle bacilli. As the disease was therefore bilateral no operative treatment was advisable.

CASE 4.*—A male, aged 20, whose only complaint was that he could see his right side to be swollen, but that never at any time had he suffered discomfort in the renal region, nor had he any recollection of urinary symptoms. On examination, there was a typical perinephric bulging in the right lumbar region, posteriorly and laterally, but there was no tenderness. Radiogram showed calcareous masses in the right renal region. The only pathological elements in the urine were a few pus cells detected microscopically. On cystoscopy, one was able to make out that the right ureteric orifice was represented by no more than a slight depression which would not admit a ureteric catheter, while on the left side there were two ureteric orifices both functioning well with effluxes of clear urine. Operation revealed a perinephric collection of clear fluid and a caseous and calcareous kidney without any vestige of parenchyma, while the attached half inch of the ureter was shrunken and difficult to identify even after dissection later (see Fig. 3). Microscopical examination of this structure showed that the lumen was completely obliterated by well-formed fibrous tissue, with scattered muscle bundles towards the periphery.

CASE 5.—A female, aged 19 years, who had complained of a painful and tender swelling in the left loin for several weeks. When I first saw her she was thin, bore a malar flush, and was running a widely oscillating temperature. There was a large tender mass in the left renal region. The patient insisted that she had never had any urinary symptoms or loin pain until suddenly taken ill a few weeks before. The urine was slightly turbid with pus. Cystoscopy showed the left ureteric orifice small and inactive, admitting a ureteric catheter only for 6 cm. I cut down on the kidney and evacuated a pint or so of greenish pus and masses of tuberculous caseous material, as a preparation for a nephrectomy later. The case was obviously one of silent, closed renal tuberculosis which had become secondarily infected.

Clinical Commentary.

Thus, to revise the outstanding features in these examples, we find we have a series of five closed renal tuberculosis cases, each with different clinical characteristics, as follows:—

No. 1. Completely silent.
No. 2. Loin pain only.
No. 3. Frequency and dysuria, pus, and tubercle bacilli in urine.
No. 4. A visible painless loin swelling, with radiographic evidence of calcification of right kidney.
No. 5. A tender renal enlargement with local and general signs of an acute infection, and some pus in the urine.

Urinary symptoms were completely lacking in two of these cases, and in a third for ten years previously if not altogether. In cases with frequency of micturition the ultimate course of this feature will be along one of two paths: either the frequency clears up completely, indicating that the tuberculous process in the kidney has become entirely shut off and the bladder lesions have healed; or the frequency persists in spite of renal occlusion in response to one of two conditions—namely, either the opposite kidney is also infected, or the bladder has become too contracted from the long-standing tuberculous ulceration to return entirely to normal. In the latter event, however, the frequency, although it continues, shows a marked improvement. Unless there is a definite clearing-up of the bladder symptoms after occlusion there is nothing to distinguish the occluded cases with frequency from the non-occluded ones with the same symptom.

It is a matter of common experience that renal tuberculosis may reach an advanced stage without giving rise to local symptoms. In 70 per cent. of Braasch's cases no loin pain was complained of. In the absence of frequency, disease of the urinary tract may never be suspected unless one of the following pathological changes occurs:—

1. Blocking of the ureter or pelvis before the functional activity of the kidney has entirely ceased, when there will be pain from distension.
2. Secondary infection occurring in the tuberculous kidney when the local and constitutional symptoms of pyogenic infection will be manifest (Case 5).[9]
3. Perforation of the renal sac by the fluid products of the tuberculous ulceration causing an extrarenal swelling, which may remain localised to the perinephric capsule, or enter the psoas sheath causing an iliac or ilio-femoral swelling.

In some cases of occlusion no complication of any kind supervenes, and the disease works itself out silently and undetected (Case 1). Braasch noted that 8·6 per cent. of 69 cases of occlusion were discovered only as a result of a general routine examination, although no urinary disease had been suspected. Swelling of the loin as the only complaint (Case 4) was noted in a number of cases reported in the literature.[10]

Of special interest are those cases of extrarenal swelling in which the mass has the same characters as a psoas abscess resulting from spinal caries. Tuffier[11] reported a case occupying the ilio-femoral region. The abscess was drained on the assumption that it was of spinal origin, and it was only on the

* I am indebted to Mr. Cecil Joll for affording me the opportunity of investigating this case.

post-mortem table that its renal source was proved. Such cases have been known to go even a stage further, and to give rise to a sinus in the lower abdomen as the presenting sign.[12] In Case 4 of my series, in which there was a visible loin swelling, the extra-renal extravasation had passed through the peri-nephric capsule and had invaded the quadratus lumborum, which showed an area of ulceration.

FIG. 2.

Photomicrograph of transverse section of upper end of ureter of Case 2. The dark patch is caseous material blocking the lumen. This is surrounded by a zone of fibrous tissue enclosed within the muscular tunic.

There still remains another clinical type of closed renal tuberculosis. In this the picture is one of chronic renal disease, often with a hypertrophied heart, an accentuated valvular second sound, and with casts and albumin in the urine. A number of these cases have been reported, chiefly by French observers.[13] Some such cases were considered to be Bright's disease, until they came to the post-mortem table, when a renal occlusion from tuberculosis was found on one side, and a simple advanced chronic nephritis on the other. The picture was carried further in two of the case reports that came under my notice, for in these the patients had both died of cerebral hæmorrhage.[14] The simple nephritis can be assumed to be due to the toxic effects of the products of the tuberculous kidney, as the association is not uncommon.

Diagnosis.

As a rule there is no obstacle to a satisfactory cystoscopy in these cases. In each of the four patients that I examined in this way the condition of occlusion was readily ascertained. A difficulty might arise from the presence of vesical ulceration, but this is not likely to be formidable, as repair is well under way if occlusion has existed for any length of time. In Case 3 I had active tuberculous lesions in the bladder to contend with, but these did not prevent me from obtaining the necessary data.

By cystoscopy there are several facts obtainable which will determine occlusion :—

1. The ureteric orifice, though visible, does not admit a ureteric catheter.
2. The ureter admits a catheter, but there is obstruction at a higher level.
3. The absence of urinary flow from the ureter.
4. The absence of dye excretion

If tubercle bacilli have not yet been identified in the urine, or tuberculous ulcers recognised in the bladder, it still has to be decided whether there is not some cause other than renal tuberculosis, for there are several other conditions which give the two last of the above findings, and one or other of the first two :—

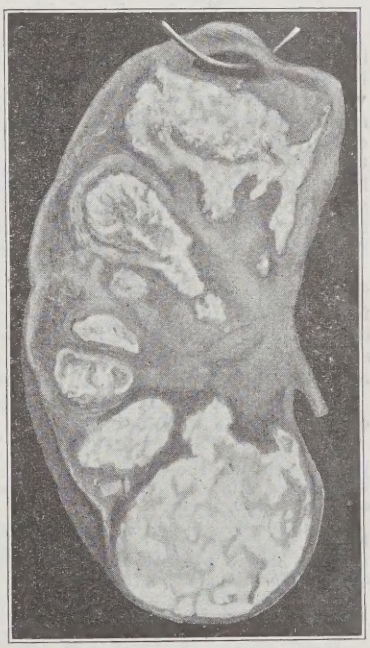
1. Congenital atrophy of the kidney and ureter.
2. Impacted stone in the ureter.
3. Primary hydronephrosis, with or without looping of the ureter over a blood-vessel.

The first is a rare condition and is not likely to be associated with symptoms. The second can be excluded by radiogram, while the third is easily decided by pyelography. As, however, nephrectomy is usually the treatment in both cases, pyelography may be considered unjustified. In all the four cases which I examined the cystoscopic signs numbered 3 and 4 were positive, while in two cases (3 and 4) the ureteric orifice in question would not admit a catheter at all. In the remaining two (2 and 5) the catheter was obstructed at different points in the lower third of the ureter. In these latter the tuberculous origin of the occlusion, although suspected, could only be proved at operation.

Radiography.—A radiogram, which should in any case form part of the routine examination, may make the diagnosis at once by revealing calcified areas in the caseous material frequently outlining the whole kidney. Braasch states that this means gave a positive result in 30 per cent. of 62 occluded cases which were examined in this way. Calcification is therefore found more frequently with the later stage of tuberculous disease than with the earlier.

Swelling in the Loin.—Extensive ulceration in the bladder, of such a degree as to prevent a satisfactory cystoscopy, may cause the surgeon to mistake a hypertrophied, perfectly healthy kidney, which is palpably enlarged, for a tuberculous one, and only on cutting down and exposing the renal organ is it made clear that the enlargement is physiological and not pathological. Under such circumstances it may be safely assumed that the opposite kidney has no functional value. I have been present when such an incident occurred. Heitz-Boyer reports the personal experience of a similar case.

FIG. 3.



Specimen of closed renal tuberculosis, showing caseous masses alternating with zones of fibrous tissue which have completely replaced the renal substance. The pelvis is a dense mass of scar without any trace of a lumen. It was through the hole indicated by the bristle that the fluid escaped into the perinephric tissues (Case 4).

In tuberculous cases generally the difficulties of getting the required information by cystoscopy can be overcome if the investigations are carried out in the proper way. First of all, spinal or general anæsthesia; secondly, the choice of the correct type of cystoscope; and thirdly, patience on the part of the surgeon, with the knowledge that several examinations may be necessary before completing the investigation.

Urinalysis.—In occluded and unilateral cases tubercle bacilli cannot be found in the great majority,

and when they are discovered in the urine, come generally from bladder lesions. The specific organism was not identified in 85 per cent. of Braasch's occluded cases. It was found in only the bilateral case of my series (Case 3).

With regard to pus and blood-cells, however, these are generally present. One or the other type of cell was detected in three of my series (3, 4, and 5). In Case 1 there was, of course, no opportunity of investigating the urine before death, but the condition of the bladder and the left ureteric orifice as found at the post-mortem examination would make it almost certain that these cells were not present, as the former had a perfectly healthy mucosa, while the latter was completely sealed off. Albumin and casts may be expected as the outstanding pathological elements when the opposite kidney is the seat of a simple nephritis as a consequence of the chronic toxæmia from the occluded side. In certain rare instances the urine drawn from the ureter of a tuberculous kidney may be free from pathological elements, owing to the fact that the focus of disease is completely encapsuled in the kidney, while the remainder of the organ excretes urine free from pus and organisms. Such an unusual contingency need only be considered when clear urine is drawn off from a kidney which has been previously proved to be the seat of tuberculosis.

The fact of diagnosing preoperatively that a tuberculous renal lesion is a closed one is of little other than academic importance. Whether open or closed the same obligations rest on the surgeon, first of all to prove the existence of a tuberculous lesion, and then to determine whether or not it is bilateral.

Treatment and Prognosis.

The non-operative treatment of the occluded kidney in unilateral renal tuberculosis has been advocated by some on the grounds that the disease has already worked out its own cure. It is quite true that the active tuberculous process may ultimately completely disappear, for Braasch was able to demonstrate that the tubercle bacilli could no longer be identified in four out of five operation specimens, which he investigated by guinea-pig inoculation. But whether the infection has ceased to exist in any given case it is impossible to say until the kidney is removed.

In those rare cases in which the disease is temporarily localised, either by encapsulation of a focus in the kidney, or by a non-permanent blocking of the pelvis or ureter although a cessation of existing symptoms may suggest a cure, a recurrence of these at a later date will show that this has not been effected.

The dangers of leaving an occluded kidney to take care of itself are threefold :—

1. There is a likelihood that tubercle bacilli are still present and are therefore liable to be carried off from the kidney to other parts of the body, and especially to the opposite renal organ.

2. Secondary infection may occur in the destroyed kidney, and give rise to an acute pyonephrosis. This may follow a trivial infection in some other part of the body, or supervene during a pregnancy.[15]

3. Continued toxæmia from the occluded organ may produce chronic interstitial nephritis of the other kidney.

With regard to operation, the same rule holds as for tuberculous kidneys generally—namely, to remove the diseased organ in unilateral infection—and only under conditions involving an urgent complication, such as secondary infection with marked symptoms, or perinephric extension, would it be justifiable to intervene surgically knowing the other side to be tuberculous. The attempt to benefit the patient by removing the worse of two tuberculous kidneys is now recognised as productive of more harm than good. Judd and Scholl,[16] in reporting on 18 such cases, state that 14 of these were dead within 18 months of the nephrectomy. Both from the point of view of post-operative mortality, and difficulties of actual removal of the kidney, the circumstances are more favourable in the closed than in the non-closed variety, in which there is still actively excreting tissue. First of all because in the closed case the opposite kidney has already been doing the whole of the renal excretory work, so that this organ has no extra strain after nephrectomy. In the second place, removal of an old-standing occluded kidney is generally an easy matter, as it presents but few perinephric adhesions, and in most cases the wound heals by first intention without drainage. With a recently occluded, or a secondarily infected kidney, however, the adhesions may be so extensive as to render the nephrectomy exceedingly difficult. When there is a perinephric abscess this should be drained first. There is a definite mortality associated with the one-stage procedure.[16]

Summary.

Closed renal tuberculosis occurs in at least 10 per cent. of renal tuberculosis cases coming to operation, but it has been found to be as high as 18 per cent. in cases reaching the post-mortem table. It is almost invariably associated with a sealing-off of the renal pelvis, on which inevitably follows complete destruction of all active renal tissue. The ureter is commonly only superficially destroyed, with its lumen occupied by fibrous tissue. The disease may go through all its stages to complete destruction of the kidney without any urinary symptoms, and in many cases is only detected as a result of some complication supervening. In others the clinical features are those usually seen with urinary tuberculosis, which, however, may disappear spontaneously. The diagnosis is not difficult if the proper methods are employed in investigating the urinary tract. Nephrectomy is the treatment of choice, and the prognosis following this procedure is good.

IRRADIATED MILK:

ITS EFFECT ON THE BLOOD.

BY VERONICA DAWKINS, M.B. BRISTOL,
AND
C. LEE PATTISON, M.B. LOND.,
KING EDWARD VII. HOSPITAL, SHEFFIELD.

RECENTLY the effects of ultra-violet light on man and animals have been investigated by many workers, both the direct effects by the exposure of patients to the rays and the indirect by giving various irradiated foods.

Ultra-violet light has been shown to increase calcification in rickets and in tuberculosis of the bone. Hess and other workers showed that the exposure of certain foods to ultra-violet light radiations conferred upon those substances antirachitic properties which they did not previously possess. Cowell [1] (working with Mellanby) then improved the calcification of bones and the general condition of rickety children by irradiating part of their diet with ultra-violet

[1] S. J. Cowell: Irradiation of Milk and the Healing of Rickets, Brit. Med. Jour., 1925, i., 594.

light. One of us has since found that similar good effects on the calcification of bones and general condition of patients with osseous tuberculosis are produced by exposing part of the milk of their diet to ultra-violet rays.[2]

Conflicting statements have been made as to the effect of ultra-violet light on the blood. Early workers showed that the number of red cells was increased, but this has not been confirmed by subsequent investigation, and is now generally considered to be due to a higher concentration of the blood. As the general health of patients having irradiated food was improved in the investigations mentioned above, it was considered desirable to determine whether in such cases any changes could be seen in the blood. Observations were made on children who had been in hospital with active bone tuberculosis for an average period of four months, without marked improvement in either general condition or local lesion. During this period they had been given the ordinary hospital diet which included cod-liver oil and 1¼ pints of milk daily, in all respects a good diet, especially from the point of view of vitamin content. The erythrocyte count and the hæmoglobin content of the blood were investigated in a number of cases from which the five patients with the smallest red cell counts were selected.

Half a pint of the 1¼ pints of the milk in the diet of these patients was exposed daily to the rays from a quartz mercury-vapour lamp at a distance of about 2 feet for half an hour. The milk was contained in shallow trays and stirred frequently. The remaining constituents of the diet were as usual. After four weeks the red cells and hæmoglobin were again estimated, and were found to have increased in all the patients. A further increase in the red cells was again noticed at the end of another four weeks, but the hæmoglobin varied. The milk was then given without radiation for another four weeks, a fall in the reds was found to have occurred in every case, and a reduction of the hæmoglobin had taken place in four out of five of the patients. The same amount of milk (irradiated) as before (½ pint) was then given daily, and at the end of three weeks the red cells had in every case increased; the hæmoglobin, however, had only slightly altered; in one its percentage was increased, in two cases it was unaltered, and in the remaining two decreased.

The following table shows the changes occurring in the number of red cells, and the amount of hæmoglobin during this period in each patient. The *average* is shown in the graph.

Case.	Age in years.	—	On ordinary milk.	After 4 weeks radiated milk.	After further 4 weeks radiated milk.	After 4 weeks non-radiated milk.	After 3 weeks radiated milk.
J. M.	5	A	*4,150	4,920	5,055	4,620	5,220
		B	68	68	62	58	54
J. G.	6	A	4,015	4,130	5,660	5,370	5,390
		B	77	78	80	72	70
A. D.	10	A	3,950	4,600	5,600	5,120	5,370
		B	79	83	80	74	74
H. B.	15	A	4,380	4,820	5,190	5,140	5,390
		B	79	80	80	80	80
E. H.	3	A	4,250	5,240	6,100	4,850	5,320
		B	80	83	88	70	72

A = Red cells per c.mm. B = Hæmoglobin percentage.
* Represents millions in each instance.

The improvement in the happiness and general health of these children after eight weeks radiated milk was extremely marked; the local lesion had also improved.

J. M.—General condition greatly improved. Local condition, as shown by clinical examination and X rays, definitely improved.

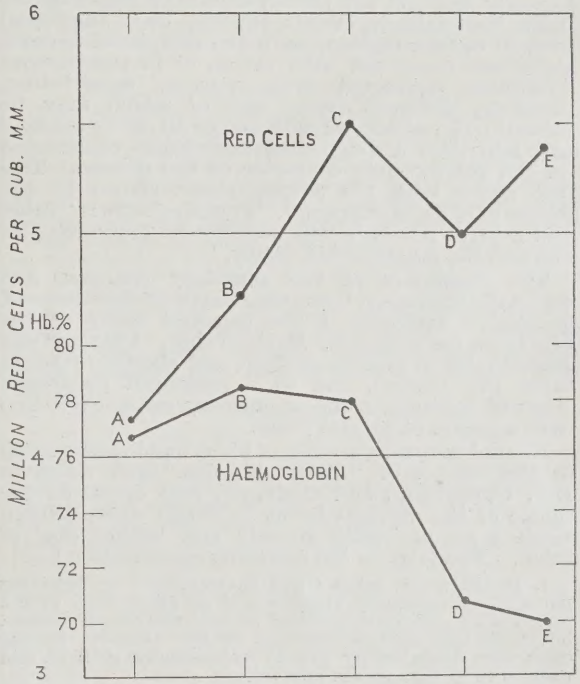
J. G.—General condition improved. Locally X rays show slight increase in calcification. Activity of hip disease less marked clinically.

A. D.—General condition greatly improved. X rays and clinical examination show that the local condition is definitely better.

H. B.—General condition greatly improved. Local condition clinically improved, but X ray shows no apparent change.

E. H.—General condition improved. Local condition as shown by X ray and clinical examination definitely improved.

The condition of the blood of six other children between the ages of 2 and 14 years, who had been on radiated milk daily for an average of ten months, was then investigated. The average red cell count was 5,030,000 c.mm., the lowest (L. S., aged 2 years) being 4,390,000 and the highest 5,970,000. The hæmoglobin in every case was high, the average being 78 per cent. and the estimations ranging between 74 per cent. (M. S., aged 12 years) to 84 per cent. (D. B., aged 9 years). This would suggest that the fall in the hæmoglobin, shown in the graph above, does not occur for long, and that the rise in the number of red cells is not continued above a certain point.



A B = radiated milk four weeks; B C = radiated milk four weeks; C D = ordinary milk four weeks; D E = radiated milk three weeks.

In estimating the red cells the blood was mixed with the diluting fluid thoroughly by shaking for two minutes. In order to ensure accuracy two estimations were made on each occasion, in each of these five sets of 16 squares were counted, so that the total number of sets was ten. For the hæmoglobin the Gowers-Haldane hæmoglobinometer was used, and two estimations were made.

Although the number of cases investigated is, of course, too small for any generalisation to be made, the results in the five patients mentioned were so definite that further work in this direction may be desirable.

ATYPICAL TABES.*

CLINICAL VARIATION IN THE COURSE OF THE DISEASE.

BY IVOR J. DAVIES, M.D., F.R.C.P. LOND.,
LECTURER IN NEUROLOGY TO THE WELSH NATIONAL SCHOOL OF MEDICINE; ASSISTANT PHYSICIAN, CARDIFF ROYAL INFIRMARY.

Tabes dorsalis is of all diseases the most unequivocal in its manifestations. The variations in the course of the disease are numerous, and constitute many different clinical types. The atypical forms are as frequent as the classical type—"l'ataxie locomotrice progressive" of Duchenne. The irregular forms appear to occur more frequently of late, perhaps as a result of the modern treatment of syphilis; this question will be later discussed. Mott[1] insisted on the unity of tabes and general paralysis in these terms: "I maintain that ætiologically and pathologically there is *one tabes* which may begin in the brain (especially in certain regions), or in the spinal cord in certain regions, or in the peripheral nervous structures connected with vision, or in the nervous structures connected with viscera, constituting, therefore, different types, any of which may be present or be associated with one or all of the others," and later this distinguished neurologist commented on the polymorphic character of the disease. This fact agrees with the polymorphism shown by the lesions of syphilis in general. Fournier[2] says: "Tabes and general paralysis will be different expressions of one and the same morbid entity."

The constancy of the pupillary changes, and especially the Argyll Robertson pupil, affords the most conclusive evidence of the essential unity of the affections designated by Mott—Tabes. Charcot[3] and Marie[4] refer to mild, imperfect, and abortive cases of tabes (*cas frustes*), and to a prolonged prodromic stage of lightning pains in ordinary cases, extending over a period of several years.

Nonne[5] devotes a section of his valuable monograph to the subject of "Tabes Atypica," and refers to Erb, Oppenheim, and Gerhardt, who discussed the theme of the atypical forms in Berlin when demonstrating an unusually chronic and benign case of tabes. Nonne gives the following classification:—

1. Rudimentary tabes (Erb) characterised by lightning pains of extraordinary violence and duration, even over a period of 20 years or longer, and without any objective signs, but with ultimate development of the disease. Similar cases were described by Erb at Baden-Baden in 1900, and caution in prognosis was advised.
2. Abortive or quiescent tabes (?) showing pupillary anomalies with isolated loss of the patellar reflexes, but which may equally be due to healed meningitic or meningomyelitic lesions.
3. Isolated ataxy without other objective signs, or subjective complaints.
4. "Tabes atypica" showing the usual alteration in the pupillary and patellar reflexes, an irregular disturbance of sensation, and a slight disturbance of the bladder. Energetic specific treatment prevents the development of further signs, and more especially ataxy.
5. Isolated gastric crises.

Nonne refers to the contribution of Dunger,[6] who stated that gastric crises may be an early symptom of the disease. The pupillary and patellar signs of tabes may be present or absent, but a pleocytosis of moderate or marked degree is usually present. Nonne's cases in this group were observed before the other reactions of the cerebro-spinal fluid were known. He recommends a cautious attitude (*toujours en vedette*) in such cases before the outbreak of tabes.

Clinical Records.

Rudimentary or Abortic Tabes.

CASE 1.—Male aged 63. Contracted syphilis at 35, inadequate treatment. Onset of severe lightning pains ten years later, which persisted unchanged for 20 years. A man of marked literary ability. He had seen Bastian who made a diagnosis of "abortive tabes," and also Gowers and Ferrier, who concurred with Bastian's view. The treatment of their day was thoroughly administered. He was entirely free from other signs of tabes except for sluggish pupils and knee-jerks for at least 15 years. He came under the care of the writer for the last two years of his life. Pupils unequal and reacted sluggishly to light. Knee-jerks unequal and sluggish. Slight sensory disturbance of legs. Occasional nocturnal enuresis which gradually became worse. Ataxy absent throughout. W.R. negative in C.S.F. and blood, other details of C.S.F. unknown, refused another examination. Suffered from lightning pains of great severity and general distribution; worse at night, and of fairly frequent incidence along ulnar area of upper limbs. Duration: 20 years, and death from the effects of cystitis.

Mild or Quiescent Tabes.

CASE 2.—Male aged 63. Missionary. Primary sore on finger "whilst acting as midwife" in Madagascar. Onset of tabes ten years later. Lightning pains, moderately severe, appeared early, and persisted, but abated later. Complained of a "facial stiffness" causing difficulty in articulation. This, which incapacitated him when home on furlough nine years later, was probably an ataxic condition, for there was no tremor or spasticity. Argyll Robertson pupils and absent knee-jerks. No ataxy, but slight Rhombergism. No anæsthesia. Occasional slight nocturnal enuresis for several years, and micturition a little precipitate at times during the day. W.R. of blood negative. C.S.F. not examined. Returned to active work in Madagascar for five years, but for three years had difficulty in micturition with occasional incontinence. Sent home as a probable case of prostatic obstruction, and admitted to King's College Hospital under Sir John Thomson-Walker and also seen by Dr. Kinnier Wilson. The following physical signs of tabes were found: Argyll Robertson pupils, knee- and ankle-jerks absent. Gait a little ataxic. Defective joint sense, and some paræsthesiæ of legs. C.S.F. showed 14 cells per c.mm. Globulin and sugar normal. Total protein, 0·05 per cent. Chlorides, 0·7 per cent. Micturition frequent and urine contained pus in considerable quantity. Complaint of stiffness and pain in facial muscles and anus. Treated for cystitis and with N.A.B. in small doses. Death occurred two months later. Duration of tabes, 15 years.

Tabo-paresis.

CASE 3.—Male aged 60. A case of optic tabes of nearly two years' duration. Bilateral primary optic atrophy. General state poor, mental state normal. Pupils equal, slightly irregular, no reaction to light, and eyes converged only on accommodation. Paresis of right external rectus muscle. Vision R.E. very poor, L.E. fair. Slight incoördination and Romberg's sign present. Sensation and sphincters unaffected. Onset with an attack of unconsciousness. He has been subject to recurrent attacks of coma of brief duration at intervals of 7 to 14 days, usually at night. No convulsion, but becomes rigid, and respiration is stertorous. No hemiplegia, otherwise these attacks closely resemble the congestive seizures of general paresis. Blood and C.S.F.: W.R. strongly positive. Globulin marked, and 35 cells per c.mm. Benedikt, who first described optic tabes, stated that the abortive cases of tabes are the ones in which optic atrophy is a prodromal symptom.

CASE 4.—Male aged 34. Served in Navy for 14 years. Primary syphilis in 1912, and received thorough treatment for over two years when he was informed that the W.R. was negative, and marriage was not forbidden. Three healthy children, and wife has had no miscarriages. Remained well until recently, when he became apprehensive owing to occasional loss of memory. Condition as follows: Anxious expression, feared insanity, evident loss of memory, mental state otherwise normal. No tremors or speech disturbance. Pupils unequal and reacted sluggishly to light but promptly to accommodation. Coördination, sensation, and sphincters unaffected. Knee-jerks obtained only on reinforcement, and were unequal. Ankle-jerks absent. Blood: W.R. a moderate positive. C.S.F. strongly positive. Globulin present. 20 cells per c.mm.

CASE 5.—Male aged 46. A case of tabo-paresis. Primary syphilis at 20 years. Suffered for several years from malaria contracted at Salonica in 1915, and last paroxysm in 1922. First seen in 1923. Depressed mental state, pupils small and Argyll Robertson type. Knee- and ankle-jerks absent. Slight Rhombergism only. W.R. a feeble positive in blood. C.S.F. not examined. Observed and treated for two years, condition unchanged until three months before death, when delusions of grandeur appeared with epileptiform convulsions which became very violent and frequent later. It is probable that the course of the disease in this case was modified by malarial infection. Death in an asylum three years from date of diagnosis of tabes.

* Abstract communicated to the Association of Physicians of Great Britain and Ireland at Newcastle-on-Tyne, 1926.

CASE 6.—Male aged 41. Duration six months. Progressive mental enfeeblement with visceral delusions. Pupils unequal and reaction to light sluggish. Absent knee- and ankle-jerks. Loss of bulbo-cavernosus reflex. No ataxy, slight Rombergism. Hypotonus slight. W.R. definitely positive in the blood and C.S.F., and latter showed a marked increase of globulin and 45 cells per c.mm.

Gastric Crises.

CASE 7.—Male aged 37. Typical gastric crises dated from 1917, when he was invalided from Salonica to Malta, where he had an operation for "appendicitis." No notes of his condition at that time were available, but he gave a clear account of periodical attacks of abdominal pain and vomiting from onset of disease, identical with those recognised later as gastric crises. It is probable that the signs of tabes were then either very slight or absent. He was sent home 16 days after the operation, and has suffered periodically from severe gastric crises up to the present time. Two further abdominal operations were performed; one in 1920 for possible adhesions, and a few were found between the gall-bladder and duodenum. The other in 1924, when tabes was first found. His condition at that time was as follows: General nutrition very poor, slight ptosis. Pupils small, irregular, and Argyll Robertson in type. No ataxy. Marked analgesia of legs. Tendon reflexes all present, except for absence of the right ankle-jerk. Knee-jerks exaggerated, especially the right. The abdominal reflexes were brisk. Blood and C.S.F.: W.R. positive. 44 cells per c.mm. Globulin absent. He suffered severely from gastric crises and an Ewald test-meal gave the following results: Free HCl, 10 units Topfer, 0·036 per cent.; combined acids, 22 units Topfer, 0·079 per cent.; total acids, 32 units Topfer, 0·115 per cent. Lactic acid present with much mucus and undigested starch cells. Squamous and endothelial cells. Yeast and a Gram-positive bacillus, probably Boas-Opler. No occult blood. On another occasion the vomited material contained no free HCl, but 0·208 per cent. total acidity, and small amounts of blood were observed in the vomit on several occasions.

Diagnosis of abdominal condition doubtful, because of severity of symptoms and extent of general disturbance, and possibility of ulcer and cancer was considered. Laparotomy was performed and some adhesions were found between the gall-bladder and the duodenum, "all viscera otherwise normal." No gastro-enterostomy found, as had been expected. The patient came under my care soon after the third operation. Physical signs much as in previous note, and left ankle-jerk still present. Marked muscular atrophy of legs (tabetic amyotrophy). Hypotonus so marked that he could place his legs around his neck. Ataxy absent until six months ago, and has since progressed somewhat rapidly. Loss of joint sense in a few toes only. Severe gastric crises occurring almost daily and only relieved by morphia. Occasional lightning pains of moderate severity for the last six months only. Blood and C.S.F.: W.R. negative. Globulin present. 20 cells per c.mm.

CASE 8.—Male aged 45. Onset of atypical tabes with gastric crises in 1918, and lightning pains for the last three years. The gastric crises occur at infrequent intervals and are of moderate severity.

Present state: General condition good, and he is continually employed except at time of crises. Argyll Robertson pupils which are also small and unequal. No ataxy in ordinary locomotion, but walks with a slightly widened base, and unable to walk a plank. Slight Rombergism. Tendon reflexes present and brisk in the upper limbs. Left knee-jerk and both ankle-jerks absent. Examination of right knee-jerk gave a very feeble muscular response only on reinforcement. No sensory or sphincter disturbance. Observed since 1925 and has had several courses of small doses of N.A.B. intravenously, and mercury and potassium iodide internally. Blood and C.S.F.: W.R. strong positive. Globulin present. Pleocytosis very slight (less than 10 cells).

CASE 9.—Male aged 44. Onset of atypical tabes with gastric crises in 1922, and now in an advanced stage of the disease. Evidence of cardiovascular change shown by slight cardiac hypertrophy, localised systolic bruit over ascending aorta, accentuated second sound, B.P. 136/90. Blood and C.S.F.: W.R. indefinite positive. 20 cells per c.mm. Globulin present.

CASE 10.—Female aged 33. Tabes commenced with gastric crises in 1922. Abdominal operation in 1916 at a large general hospital for "an affection of the womb." A second operation was performed at a Poor-law infirmary in 1924 owing to recurrent attacks of acute abdominal pain and vomiting. An inflamed appendix was removed. The uterus appeared normal, and showed no sign of previous operation. A typical case of advanced tabes. Patient confined to bed, and still suffers from gastric crises at fairly regular intervals of three to four weeks. One pupil still reacts slightly to strong illumination, and both pupils show paradoxical reaction to ordinary light. The right external rectus muscle is paralysed. The arms are ataxic and show athetosis. Marked amyotrophy of legs. Blood: W.R. very weak positive; C.S.F.: W.R. strong positive. Globulin present. Slight pleocytosis (20 cells per c.mm.).

Tabes with Epileptiform Attacks.

CASE 11.—Male aged 56. Primary syphilis at 25. No treatment. "Epilepsy" from 1915 and treated with bromides only. Major attacks for several years almost regularly once a month during sleep just before waking, infrequent of late, and now subject to petit-mal attacks at monthly intervals. Tendency to retention of urine for many years, and mild cystitis on a few occasions. Mental state somewhat feeble, no gross change. Pupils unequal and oval, inactive to light, active to accommodation. Tendon reflexes preserved and brisk, plantar reflexes flexor. No ataxy or Rombergism. Group of typical scars of past syphilitic lesions on back of left forearm. Irregular thickening of crests of tibiæ. Analgesia of tendo Achillis (Abadie's sign), and of ulnar nerve at elbow (Biernacki's sign). Blood and C.S.F.: W.R. definite positive. Globulin present. 35 cells per c.mm. The disease appears to have been quiescent, but valuable time was lost before the administration of antisyphilitic remedies.

Aortic Incompetence with Quiescent Tabes.

CASE 12.—Male aged 49 years. Duration of heart affection 10 years. Lightning pains in legs for several years past, otherwise free from symptoms of the nervous affection. Aortic incompetence, moderate lesion, probably syphilitic in origin. Extreme arteriosclerosis of peripheral vessels. Blood pressure: Arm, 210/90. Leg, 260 systolic. Pupils unequal and show Argyll Robertson phenomenon. Tendon reflexes absent in lower limbs except for slight response in quadriceps on reinforcement. Coördination, &c., normal. No ataxy in locomotion or Rombergism; inability to walk a straight line or stand on one foot; slight loss of joint sense in toes only; sensation and sphincters normal; W.R. in blood and C.S.F. strongly positive. Pleocytosis (56 cells per c.mm.). Globulin present in definite amount. Lange's colloidal gold reaction showed a typical paretic curve.

Cases of Arthropathy with Evidence of Tabes.

CASE 13.—Male aged 50. A bilateral severe affection of the knee, two years' duration, gradual onset, almost painless throughout. An arthropathy of the right wrist of three years' duration. The knee-joints were symmetrically affected by a synovial effusion of almost maximum extent. The skin was pale, thinned, and marked with prominent veins. Marked muscular arthropathy, especially of the legs and of the quadriceps muscles. Uniform swelling of the synovial sac without thickening of the membrane. No loose bodies felt. Movements fairly free, painless but crepitant. Slight lateral mobility only, and no hypotonus of the limbs. Puncture revealed a straw-coloured glairy fluid, free from blood. The wrist-joint was slightly and irregularly swollen, and almost fixed. Moderate atrophy of right thenar eminence and of first dorsal interosseus muscle. A skiagram of the knees showed absorption of cartilage with some atrophic bony change. No osteophytic growths. The bones of the affected carpus were almost adherent, the interarticular spaces being much narrowed and indistinct.

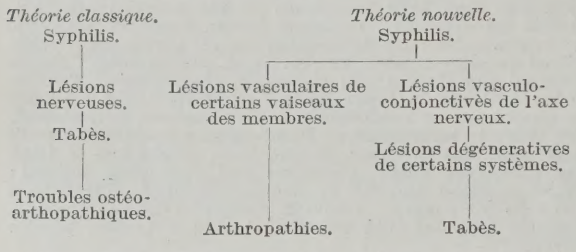
A general examination showed marked emaciation, patient being almost cachectic. Pupils unequal, and of oval outline. Bilateral Argyll Robertson reaction. All reflexes normal. No disturbance of joint sense, coördination sensation or of sphincters. Definite history of syphilis at 20 years of age, and was treated for three months only. Lightning pains of moderate severity in the lower limbs for the past three months. W.R. of blood and C.S.F. negative, and latter was otherwise normal.

CASE 14.—Male aged 60. Primary syphilis at 23, and inadequately treated. Lightning pains moderately severe at infrequent intervals for the past 25 years, and attributed to "sciatica and neuritis." Micturition somewhat precipitate for several years, and nocturnal enuresis on several occasions. Loss of feeling in left thumb and right little finger. Arthropathy of right knee, 12 weeks' duration, followed injury through fall, and knee was much swollen and painful. History of similar swelling of six months previously without injury, and which subsided in a few weeks. Extensive synovial effusion of right knee. Marked lateral mobility with crepitus. Many nodules felt, probably loose bodies. Skiagram showed destructive bony change in articular extremities, especially in outer head of tibia and external condyle of femur. The upper end of the fibula showed considerable loss of substance, and was completely separated from the shaft. Marked periostitis of upper third of fibula, and over lower third of femur. General state good. Pupils

reacted very sluggishly to light, a fair response to accommodation. Both knee- and ankle-jerks absent. Some blunting of common sensation of left thumb and right little finger. Abadie's and Biernacki's signs present. W.R. of blood and C.S.F. negative. Globulin absent. No pleocytosis.

Case 13 is one of the varieties of articular syphilis and probably of the nature of chronic synovitis. The characteristics are not those of a gummatous synovitis (infiltration gommeuse périsynoviale de Lancereaux) which usually responds well to anti-syphilitic remedies. The case in question has shown no improvement after such treatment. The effusion in its appearance and extent was similar to that usually found in Charcot's osteoarthropathy. The other signs are probably sufficient to warrant a diagnosis of abortive tabes. Case 14 resembles the osteoarthropathy of Charcot more closely than one of the other forms of articular syphilis. The general signs are those of rudimentary or abortive tabes. The cases are included to present Barré's[7] view that Charcot's osteoarthropathy is not peculiar to tabes, but is a syphilitic condition. He reports numerous cases of osteoarthropathy where there was no evidence of tabes: *l'arthropathie à type tabétique du syphilitique non tabétique.*

Barré[7] submits what he calls the classical and new theories in a tabular form.



The first case of the present contribution is definitely not one of osteoarthropathy, but mainly one of synovitis, and of probable syphilitic origin, for there is no evidence of tuberculosis, and the characters of the knee affection are not altogether those of rheumatoid arthritis. The association with tabes is apparently coincident. The second case is an osteo-arthropathy similar to that described by Charcot, but unilateral, and painful in its development. The condition of tabes is rudimentary only, and unless a premises of gross trophic periarticular change is assumed solely around one joint, then the arthropathy is clearly not of tabetic but of syphilitic origin.

Remarks.

It would be more correct, perhaps, to group these various forms under a comprehensive title of tabes, than to distinguish them as an atypical class. The irregular or incomplete forms appear to be more numerous of late, as Nonne affirms. He surmises whether this is due to a more thorough treatment of syphilis, earlier diagnosis of tabes, or alteration in the character of the disease. The first assumption is excluded, because most of his cases had only an imperfect cure of former lues. It is rational to believe that early and energetic treatment of the cause must influence the incidence of its effects, but such is not invariably the case with syphilis, as most authorities are agreed. The other assumptions may be true, for, as Nonne suggests, earlier diagnosis would protect the patient from excesses which would be prejudicial to his progress. He also reminds us of the fact that general paralysis now occurs oftener in the form of simple dementia than as "classical paralysis."

Salvarsan was introduced by Ehrlich in 1906, and gave an impetus to a more thorough general treatment of syphilis. Neurologists may now be in a position to estimate the influence of modern treatment on the incidence and character of tabes and other forms of cerebro-spinal syphilis. If early diagnosis of tabes leads to its amelioration, then we must try to define its symptomatology more precisely. In the absence of a pathognomonic sign, or choice of a minimum syndrome, we must rely on almost conclusive elements of diagnosis. This was the view of the Society of Neurology[8] in Paris in 1911 at a special session devoted to the subject of "délimitation du tabès." The fundamental signs and symptoms are well known. Mott states:

"The fundamental symptoms and signs of tabo-paralysis and of tabes are: (1) Reflex pupil rigidity. (2) Lightning pains. (3) Absence of deep reflexes. (4) Visceral disturbances, bladder troubles, and gastric crises. (5) Disturbances of sensibility. (6) Motor disturbances. (7) Mental disturbances."

Mott further says that "a diagnosis can be made if the pupil rigidity exists, combined with any of the others." Gowers[9] points out that the Argyll Robertson pupil may be the sole sign. One or more of the other signs generally appear sooner or later. The Argyll Robertson pupil is for all practical purposes pathognomonic of the group of affections called by Mott—tabes. The light reflex is the most sensitive of all the reflexes, and is particularly susceptible to the action of the syphilitic toxin. These facts, perhaps, account for its early loss in tabes.

Sir John Rose Bradford, in his teaching at University College Hospital, maintained that the Argyll Robertson pupil meant (1) syphilitic infection, (2) syphilitic affection of the nervous system. This sign has been reported to exist in some cases of chronic alcoholism and other diseases by authors quoted by Barré[7] and Purves-Stewart.[10] Mott, in this connexion, says "of alcoholism and other diseases . . . these cases are complicated by syphilis." The unreliability of the W.R. in tabes makes it very difficult to exclude the disease absolutely. A sluggish pupillary reaction to light without other ocular abnormality should be regarded with suspicion. Loss of the normal pupillary unrest (Hübner[11]) referred to by Purves-Stewart may be one of the earliest signs of organic affection of the reflex visual path—e.g., in tabes or general paralysis.

Barré[7] suggests the following rule in diagnosis: "There is tabes when with the Argyll Robertson sign is associated at least one of the triad (Argyll Robertson sign, cerebro-spinal lymphocytosis, abolition of an Achillis reflex)." Nonne[5] emphasises the importance of confirmatory methods (*Auswertungsmethoden*) and in particular the four reactions (*vier Reaktionen*)—viz., the W.R. of the blood and cerebro-spinal fluid, lymphocytosis, and the presence of globulin (phase 1 Nonne) in the fluid. Barré says: "The Wassermann reaction with 0·2 c.cm. of the cerebro-spinal fluid is very inconstant in cases of tabes, and one cannot rely on it to affirm or deny the existence of this malady," and most authorities will agree with this statement.

Lymphocytosis arising from a chronic meningeal reaction is not specific of tabes or even of syphilis, for it occurs in other diseases, and more especially as Nonne[5] states in caries of the spine with compression of the cord, and sometimes in other non-syphilitic varieties of compression myelitis. This sign is more constant and marked in parenchymatous syphilis than in the other named conditions. The fluid above the obstructed area in cases of compression is usually normal. The four reactions and especially the Wassermann reaction are more marked in cases of tabo-paresis, or when cerebral symptoms are prominent. The Wassermann reaction may be positive in the cerebro-spinal fluid when negative in the blood, as Mott showed many years ago. These reactions as a rule correspond with the clinical condition, but are not always in agreement, as was shown in the second case of gastric crises where the Wassermann reaction in the blood and fluid was strongly positive, although the disease appears to be quiescent, and there was little or no pleocytosis, and conversely in Case 3. The ankle-jerks disappear before the knee-jerks, as was first shown by Babinski. These reflexes should be systematically and methodically examined. A sluggish response precedes loss, and one goes generally before the other. The knee-jerk is more easily examined, but with a precise method of examina-

tion the ankle-jerk is quite as easily obtained in normal individuals.

Increase of protein in the cerebro-spinal fluid occurs in cases of parenchymatous syphilis, and in all forms of spinal compression. The protein found in the former group of diseases is globulin, and constitutes the "phase 1 reaction of Nonne." The other signs of tabes should be investigated, and in particular a careful search made for early signs, as insensitiveness of the tendo Achillis to firm pressure (Abadie's sign), loss of the cremasteric reflex, or of the bulbo-cavernosus reflex. Disturbance of the sphincter urinæ shown by a tendency to retention sometimes occurs early, and a little residual urine may be found. Such cases were called by Guyon "false urinary patients." Marie [4] refers to Fournier, who says "these patients only pass water in several acts."

Mott[1] includes lightning pains in the list of fundamental symptoms and signs, and Barré [7] attaches "a great importance to the fulgurant pains when these have a well defined character." Charcot[3] says, "during long years these pains may of themselves alone compose the entire symptomatology of the disease."

The pains of peripheral neuritis, especially when due to alcoholism and arsenical poisoning, may simulate the lightning pains of tabes, but as Marie [4] says, "they have not precisely the same characters as the lightning pains of tabes." The pains are more specially seated in the muscles, and increased by pressure, and less fugitive, and but rarely occur paroxysmally. The root pains of extra-medullary tumours are alone comparable in intensity to the lightning pains of tabes. The characteristics of gastric crises have been well defined by Charcot,[3] Marie,[4] Dunger,[6] and others.

Review of Cases of Gastric Crises.

The principal features shown by the cases included in this contribution were :—

1. The patients were ill-nourished, or even emaciated, and much debilitated.
2. An abrupt onset and termination of the attacks.
3. Duration usually prolonged over the period within which peritonitis is probable in other acute abdominal states.
4. Periodicity was well shown in one case where the attacks occurred for years regularly on waking.
5. Variability in duration and intensity of attacks when observed over a long period. Earlier attacks only in cycles.
6. Rapid recovery of the digestive functions so that the patient often takes a full meal within an hour of cessation of a severe attack. This was a feature of three of the cases, but one patient complained of nausea for several days after the more severe attacks.
7. The general disturbance at the height of a paroxysm closely resembles that of the common acute abdominal states.
8. *Extreme restlessness*, the patient writhes in agony, and rolls about in pain, and assumes various postures in an endeavour to secure relief—e.g., Case 1 was found several times in a self-imposed trussed-up position, with his legs around his neck. This state of restlessness in cases of gastric crises is in sharp contrast with the immobility of the ordinary "acute abdomen."
9. A mental state of acute misery, and bedclothes often drawn over the head, and examination resented.
10. Distribution of pain more that of a gastro-enteralgia, and pain is relieved by pressure.
11. Absence of localised tenderness and rigidity. Examination difficult and apparent localisation of signs in epigastrium or elsewhere most inconstant and untrustworthy.
12. Absence of distension, abdomen being usually retracted.
13. Isolated attacks of pain without vomiting, described by Fournier [2] as a cramp-like pain.

A routine examination is likely to disclose the cause—tabes—even when the disease is in an early stage, as shown by one or more of the physical signs already described. The cerebro-spinal fluid should be invariably examined in suspected cases. Confusion with acute abdominal emergencies only arises in earlier attacks. The ordinary acute abdominal affections may occur in tabetic patients, and may be painless throughout, as we are reminded by Purves-Stewart.[10]

The main objects of this paper are : (1) To draw attention to the prevalence of the irregular manifestations of tabes. (2) To support the principles of treatment advocated by Buzzard[12] in his Lettsomian lectures. Syphilis is, as he says, a lifelong disease. Sufferers should be subject to supervision for the remainder of life. The advantages and possible disadvantages of such a plan were ably suggested in a subsequent editorial article in THE LANCET.[13] A feeling of security engendered in a majority would far outweigh any possible disadvantages to a minority. Such a policy would certainly result in at least an amelioration of the late sequelæ of syphilis.

I am much indebted to Dr. W. Parry Morgan, of the Cardiff and County Public Health Laboratory, and to Dr. H. A. Scholberg, pathologist to the Cardiff Royal Infirmary, for their examinations of the blood and cerebro-spinal fluid in the illustrative cases.

Medical Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

A MEETING of this Section was held on Nov. 26th, with Mr. R. C. B. MAUNSELL (in the absence of the President) in the chair.

Mr. H. S. MEADE showed a specimen of

Carcinoma of the Pelvic Colon involving the Bladder.

The patient was a woman, aged 69, sent to him on March 19th, 1926, for cystoscopy. Immediately after a motor accident in June, 1925, she noticed that she was obliged to sit sideways when she wished to pass water, but this symptom passed off. At the time of examination she said that for 18 months she had had frequency of micturition, accompanied by scalding pain. This trouble had been growing steadily worse, and she had to pass water every hour both day and night. The urine contained albumin, bacteria, and a few leucocytes.

On March 20th an attempt at cystoscopy was made, but the result was unsatisfactory, owing to the patient's nervous state and to the fact that the capacity of the bladder was only half an ounce. Any dilatation caused extreme pain. No sign of inflammation was seen. The patient was kept in bed and gradual dilatation tried. She refused an anæsthetic until March 29th, when cystoscopy was done. The bladder dilated up to 8 ounces easily, and there was no evidence of any inflammation except the congestion of the trigone so often seen in the female bladder. Chromocystoscopy with indigo-carmine showed the dye coming from the right kidney in five minutes and from the left in four minutes.

Rectal and bimanual examination revealed a mass on the left side of the pelvis in the region of the left broad ligament ; it extended above the brim of the pelvis and appeared to be well fixed. A sigmoidoscope was passed, and a carcinoma of the pelvic colon found. Owing to the age of the patient, the fixity of the growth, and her terror of operation, it was decided to treat her with deep X rays. On April 6th Dr. M. R. Hayes gave her a dose of 100 per cent. X rays, estimated by Holdfelder's field selector and calculated by Solomon's iontoquantimeter. It was administered in two portions on April 6th and 7th, the factors being as follows : wave length, A.U. 09 ; field, 12 × 10 cm. ; focal skin distance, 30 cm. ; filter, 0·5 mm.

with 2 mm. aluminium. Irradiating from the front, one field was over the left Poupart ligament and the other over the right on the first day. On the second day one field was through the centre of the sacrum from the back, with two smaller ones on either side of it. The factors for the smaller fields were: 6 × 8 cm. F.S.D. 23 cm. The exposure for the larger field was 60 minutes and for the smaller one 35 minutes.

The treatment was borne well. Dilatation of the bladder had relieved the frequency of micturition, which returned in a milder form one week after the X rays, but passed off in a few days. The patient said that she was much better, and there was a definite shrinkage in size of the tumour. The irritability of the bladder returned on May 26th, but was relieved by urinary sedatives. On May 31st and June 1st the deep X ray treatment was repeated, reversing the fields with the same factors. No disability followed the treatment other than the usual transient anæmia, which readily responded to hæmatinics, and a feeling of tiredness which lasted a few days.

On June 10th the patient thought that she was passing gas from the bladder. Another cystoscopy was done, and on the left upper lateral side of the bladder a small area of inflammation (1 cm.) was found, in the centre of which there was a pinhole fistula. There was no sign of any gas or any evidence of fæces in the urine or the bladder. Seen again later, the patient was in great distress, passing large quantities of gas, especially on micturition, which was accompanied by a whistling sound that could be heard at some distance and over which she had no control. It was decided to perform a colostomy to prevent the entrance of fæces into the bladder, and on June 16th the abdomen was opened and the growth was found lying on the left side of the bladder. The uterus was retroverted and atrophic. The left tube and ovary were fixed to the growth and œdematous, as also was the colon. The tumour was reduced one-third in size since first discovered, and also more mobile, and it was therefore decided to remove it. To do this it was necessary to remove more than a third of the bladder with it. The bladder was closed with three layers of sutures and muscle-splitting colostomy was done. A catheter was inserted in the cæcum for the introduction of saline, the abdomen closed, the pelvis drained, and a Poussin catheter inserted in the bladder. With the exception of a slight attack of phlebitis in the third week the patient made an uninterrupted recovery.

Dr. T. T. O'Farrell reported that the growth was a so-called colloid carcinoma, associated with a considerable amount of inflammation. Sections taken through an adherent piece of bladder showed much inflammation, but no carcinomatous element could be found in this piece of material. On Oct. 28th the patient reported that she was in excellent health. "All organs are acting normally, and the side appliance gives me very little trouble." She had gained a stone in weight and had completely lost her nervousness.

Mr. Meade explained that he had shown the specimen in the first place because of the difficulty of diagnosis. Even when the growth had been found the patient had given no definite symptoms of carcinoma. She had been constipated and had passed some mucus and blood, and had some pain over the left side of the abdomen, but she had been rather indefinite about them. The second reason for reporting the case was that the treatment by deep X rays had made it possible to operate on a tumour which was clinically inoperable. Thirdly, the fact that a growth involved the bladder and a fistula was present should evidently not deter the surgeon from operative interference.

Sir WILLIAM WHEELER read a paper on

Thrombo-angiitis Obliterans,

based on an experience of two cases, in one of which the diagnosis was certain, whilst in the other the absence of pathological examination made the differential diagnosis from Raynaud's disease difficult. In both cases, said Sir William Wheeler, the disease occurred in Irishmen who had served abroad. Those who had made this remarkable disease a special study insisted that it almost exclusively occurred in male adult Jews, especially those amongst the poorer class who had migrated from Russia. For no accountable reason an inflammatory condition arose in the deep arteries, and often in the veins, which after weeks, months, or years led to thrombosis and obliteration of the vessels, with disastrous consequences. The disease was presenile, non-syphilitic, and non-embolic.

CASE 1.—The patient was an officer who had served for some years in Egypt. The condition was acute, and the outstanding features of the case were typical—sudden pain in the muscles of the calf of the intermittent claudication variety, flushing of the foot in the dependent position, and an unbearable pain, associated with blanching of the foot when it was raised. All the vessels round the foot were pulseless. The age of the patient was 28. He was strong and athletic. From the time of the first sudden pain the circulation in the foot became more and more precarious until finally gangrene developed in the toes, accompanied by lymphangitis and infection, and it became necessary to amputate above the knee. The entire course of the disease, so far as symptoms were concerned, was three weeks. Examination of the vessels of the amputated limb showed occlusion of the popliteal artery one inch below the level of the amputation, and also characteristic changes in the vessels of the leg and foot. The deep veins were also thrombosed and to some extent calcified. An attempt at restoration of the circulation by canalisation was found by Dr. O'Farrell. Leriche's operation was tried, in addition to vigorous conservative treatment, but without effect.

CASE 2.—The other patient, who was shown at the meeting, had been under an anæsthetic 30 times, and had undergone about 40 operations within 10 years. The lower limbs and the upper limbs were affected. He had served in the Navy throughout the war, and was of fine physique. The disease was now quiescent, but the man had lost both lower limbs—one below and the other above the knee. The first finger of the right hand had gone and the tips of the fingers of both hands were involved. After the patient had suffered from numbness, blanching, and rubor, with intense pain, for four years, the great toes—first in one foot and then in the other—became gangrenous in 1919; from this time until the present he was in and out of hospital, having amputations performed now on one limb and now on another.

The outstanding features in the history of the two cases, said Sir William Wheeler, were that (1) neither was a Hebrew; (2) neither had syphilis; (3) both served abroad; (4) both were heavy cigarette smokers; (5) the chronic case lost portions of all four limbs over a period of ten years; (6) the acute case lost the left leg above the knee within three weeks of the first attack of pain in his calf; (7) both patients were strong, active men under 30 years of age. The disease never occurred in women. Cigarette smoking must be considered as a causative factor. The disease only occurs in inveterate smokers, and Weber had found several cases where the victims were employed in cigarette factories.

Dr. T. T. O'FARRELL showed a series of lantern slides illustrating the cases. He said that the trouble in Case 1 had started in the great toe, and had spread upwards. The tissues were œdematous, and there was some exudation of blood. The upper part of the popliteal artery was normal, but the lower part was thrombosed. Most of the arteries of the limbs showed fibrosis of the muscular coat, with the exception of the peroneal, and several of the veins showed commencing calcification. Attempts at canalisation of the clot were found here and there in the tibial vessels.

Mr. MAUNSELL said that he thought that smoking was now too common a thing to be attacked and put down as the possible cause of any disease. Both the patients described had been Irishmen, but they had both been abroad. This fact suggested to him that the condition might be due to microbial infection.

Mr. C. J. MACAULEY asked whether in Case 1 the possible diagnosis of Raynaud's disease and peripheral gangrene had been considered. He thought that possibly the disease might have originated from an embolus.

Mr. W. PEARSON referred to a case somewhat similar to those described by Sir William Wheeler.

The patient was a farm labourer, aged 38, who previously had been perfectly healthy, and had never been abroad; he never smoked cigarettes, but always a pipe. The gangrene was dry, but spreading rapidly, and affected the left limb. Mr. Pearson did a supracondyloid amputation, and the man had remained quite well ever since The Wassermann reaction had been negative, and there had been no sign of arterial disease elsewhere in the body.

Mr. MEADE referred to two cases of arterial gangrene which he had treated.

Sir WILLIAM WHEELER, in reply, said that in making the diagnosis embolism was discussed, but was not seriously entertained. In the first place, obstruction from an embolus might produce the symptoms described in a young man, but if the limb survived the first few days the collateral circulation would be rapidly established, and all anxiety would have disappeared within the first fortnight. As a matter of fact, the circulation in Case 2 became more precarious daily for three weeks, until gangrene finally appeared. In the second place, there was no discoverable lesion from which an embolus would come. The pathological examinations later proved the correctness of this point of view, and established the fact that a true thrombo-angiitis obliterans existed. Raynaud's disease was difficult to exclude as a possible explanation in Case 1. Nevertheless, Raynaud's disease commencing in the toes, in a strong man of 25 years of age, was exceptional, and the patient was the exact reverse of the type of individual in which the Raynaud syndrome was to be found. No pathological examinations were made, and he did not definitely exclude the possibility of Raynaud's disease. In Case 2 the diagnosis of thrombo-angiitis obliterans was certain. It was made before operation, and the pathological examinations were conclusive. He had had a fairly large experience of the Leriche operation. It produced many of the effects claimed, but the physiological reasoning on which the operation was based was open to criticism.

Mr. MAUNSELL showed a teratoma removed from the transverse colon of a girl of 17, and a specimen of

Diffuse Hæmangioma of the Liver.

The patient was a man, aged 26, who had come to hospital stating that two days previously, while at a fair, he had got weak, and had gone into a friend's house, where he became weaker and had abdominal pain. He was seen by a doctor, who thought he was suffering from perforation, possibly of a gastric ulcer. When seen by Mr. Maunsell he was absolutely blanched; the abdomen was distended, and seemed to have fluid in it. When it was opened this fluid was found to be pure blood. A bleeding point was looked for unsuccessfully, but the blood seemed to be coming down from the liver. Next day blood transfusion was done, and the patient did well. After a slow convalescence he was allowed up, but he never had a perfectly normal temperature. One day, while up, he again felt faint, and was put back to bed, and from that time onwards he ran a higher temperature. A radiograph showed that the diaphragm was higher on the right side than on the left; a needle was inserted, and bloody fluid found. A rib was then resected, and only blood escaped. A tube was inserted; the patient apparently bled internally and died.

LIVERPOOL MEDICAL INSTITUTION.

AT a meeting held on Nov. 25th Dr. H. S. PEMBERTON read a paper on

Arthritis Deformans: Its Ætiology and Treatment

in which he gave an account of investigations carried out by Dr. L. S. Ashcroft, Dr. L. Cunningham, Mr. T. P. McMurray and himself. After referring to the difficulty of diagnosing the condition from other forms of arthritis, with the exception of monoarticular and menopausal forms, which were included, Dr. Pemberton said, that 64 cases had been studied, from the clinical, the bacteriological, the metabolic, and the therapeutic standpoint. It had been found clinically that cardiovascular changes were relatively infrequent. Little or no change had been discovered in the rate of intestinal passage, nor was there any evidence of renal inefficiency. The degree of hepatic efficiency was doubtful as, although there had been no excess of urobilinuria, the blood-lævulose curves had indicated abnormality; sulphur excretion was definitely increased; 65 per cent. of the fractional test-meals had shown hypochlorhydria (50 per cent. of these being achlorhydria), and the glucose tolerance had been found impaired in practically every case. The basal metabolic rate varied very little. Dr. Pemberton showed illustrations comparing blood-glucose curves in arthritis with those in normal diabetes, and in pancreatic disease, and said that the latter were found to resemble most closely the curve in arthritis. He also showed pictures of bone and joint changes in diabetes mellitus. On the therapeutic side, he said, the aim had been to make good or counteract deficiencies which the investigation had shown to exist—i.e., deficient gastric secretion, diminished glucose tolerance, and increased sulphur loss. This had been done by giving as a routine: (1) large quantities of 0·4 per cent. pure hydrochloric acid; (2) a carbohydrate-free diet of low calorific value, increased later by the addition of more fats, proteins, and some of the 5 per cent. carbohydrate foods; (3) collosol sulphur; (4) massage and then exercises. Dr. Pemberton referred to the difficulty of taking a carbohydrate-free diet over a long period. By the results, which had proved very encouraging in some 60 to 70 per cent. of the cases, and sometimes within so short a period as three weeks, it was felt that such therapy was distinctly valuable.

Mr. C. O. DAVIES read a note on

Recurring Acute Intussusception

in which he described the main features of a case which had recently come under his care. A male child, 5 months old, was operated on twice within 12 weeks. On the first occasion an ileocæcal intussusception was reduced, whilst on the second there was an ileocolic invagination. From a study of 32 cases reported in the literature, Mr. Davies had reached the following conclusions: (1) recurrence of acute intussusception in childhood is rare, at the most amounting to less than 4 per cent. of cases; (2) the usual interval between the recurrences varies from two and a half to ten months, though he had met with a few cases in which the interval was as long as two years; (3) there does not appear to be any necessity for trying to prevent recurrence, nor is there any reliable method for doing so. He laid stress on the importance of warning parents that recurrence is possible, although unlikely, and urged the necessity for immediate reoperation.

CARDIFF MEDICAL SOCIETY.

A MEETING of this Society was held on Nov. 23rd, when Dr. ALFRED HOWELL took the chair and Mr. J. BERRY HAYCRAFT read a paper on the

Diagnosis and Treatment of Gastric and Duodenal Ulcers.

He described the routine method of examination of cases in the surgical unit, which consisted of clinical history, physical examination, X ray examination, fractional test-meal, examination of stools for occult blood, blood count of red cells, blood compatibility in case of transfusion, and Wassermann reaction. He laid stress on the importance of taking an accurate clinical history of the symptoms of the disease from its commencement, and described in detail the symptoms and methods of questioning the patients. A good history was the most important means of diagnosis. X ray examination should be conducted by the radiologist and the surgeon together, and screen examinations gave a better indication of the nature of the lesion than films. The fractional test-meal had been of value in confirming the diagnosis in only half the cases, but the detection of occult blood in the fæces had made it certain in many doubtful cases.

In considering what type of operation was of most value, Mr. Haycraft emphasised especially the need for early diagnosis, which, as a rule, rendered operation simpler and less dangerous. Speaking generally, duodenal ulcers and simple ulcers close to the pylorus could be cured by the operation of gastro-jejunostomy, but ulcers on the lesser curve and those adherent to the liver or pancreas required some form of excision or partial gastrectomy to get a satisfactory result

It was in these old-standing adherent cases that partial gastrectomy was often very difficult and the mortality was higher than that of gastro-jejunostomy, but by earlier diagnosis and treatment some of these more severe operations could be avoided. Sleeve resection was not a good operation unless combined with gastro-jejunostomy. Two cases of hour-glass stomach where gastrectomy was not feasible had done well with gastro-gastrostomy combined with gastro-jejunostomy. Careful pre-operative treatment was most important, particularly the rectal administration of glucose and, if necessary, one or more transfusions of blood. Similar measures were indicated to combat shock after operation.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on Dec. 8th, Prof. WILLIAM RUSSELL, the President, in the chair.

Mr. N. M. DOTT read a communication on a

Simple Method of Intestinal Anastomosis.

He had been led to adopt this method, he said, by its simplicity and its usefulness in otherwise awkward situations. It was founded on the technique of Eck's venous anastomoses and was applicable to lateral and end-to-side union, but not end-to-end anastomosis. In lateral union the two lines of viscera were laid together and the posterior seromuscular layer stitched in the usual manner, the proposed opening in each viscus then being outlined by an incision which divided the seromuscular layers and laid bare the submucous tissue. The cut posterior edges were firmly joined by sutures, anchoring the exposed mucous membrane, and including in the stitches blood-vessels of any size. The novelty of the method lay in the next step. A long needle, carrying No. 60 commercial linen thread, was passed through the exposed mucous membrane to the lumen at one end of one of the incisions; it was then passed along the lumen and brought out at the other end of the incision. Next this same needle was passed along the lumen of the other viscus in a similar way but in the opposite direction, and thus the two layers of mucous membrane which were to form a septum when anastomosis was complete were encircled by the thread. Next the anterior part of the incision was stitched up in the same way as the posterior, but the last stitch of the inverting seromuscular suture was left uncompleted. The linen thread was now used in the manner of the Gigli saw and the layers of the mucous membrane which it included were easily and rapidly divided and the continuity of the lumina thus established, after which the final stitch was completed.

The advantages of this method, said Mr. Dott, were (1) its relative asepsis; (2) the accurate apposition of the submucous surfaces; (3) it could be carried out in any reasonable situation; (4) clamps were not required, the only instruments needed being suture needles. Hæmostasis was assured since all the vessels except the capillaries of the inner surface of the mucous membrane were secured. By modifying the method end-to-side anastomosis could be carried out, though this necessitated open exposure of one end of gut and a controlling clamp. The method was exceptionally useful in ileocolic anastomoses where the colon was fixed and difficult to approach with clamps, and it minimised the danger of severe sepsis from a stagnant colon.

Mr. W. A. COCHRANE read a paper on

Backache from the Orthopædic Standpoint,

in which he began by discussing industrial injuries of the back. The first thing to be noted, he said, was that people might engage in industries for which they were physically unsuited. The slender, small, and delicate type of anatomical structure was inappropriate for bearing heavy weights. Secondly, back strain might arise during either light or heavy work in persons using their body at mechanical disadvantage. Incorrect bodily mechanics paved the way for strain of the dorso-lumbar, lumbo-sacral, and sacro-iliac regions. In the examination of cases a radiogram might show no evidence of an intrinsic lesion, and in such an event a detailed physical examination was of the first importance. It was wrong to take up the attitude that because X rays revealed nothing the patient could have nothing the matter. In point of fact, however, careful stereoscopic films would often supply the evidence sought for. A further problem which merited attention was that arising from the chance discovery, after radiography of the spine in cases of alleged trauma, of a definite lesion, such as osteoarthritis or compression fracture. In such cases the question of compensation might lead to endless argument in the midst of which the patient too often got no definite treatment. In considering the relationship of the common anatomical abnormalities in the lumbo-sacral and sacro-iliac regions to alleged injury, Mr. Cochrane took up the view that they were to be regarded as potentially contributory in the determination of the onset and persistence of symptoms. Malingering presented a difficult problem. Two factors must be discounted before concluding that the patient was malingering; first, his probable misconception of the ætiology of his condition, and secondly, his apprehension that, even in the genuinely painful back, he had no tangible and visible evidence to produce. Mr. Cochrane believed that as more was learnt about the proper methods for conducting a systematic routine examination it would be found that the real malingerer was not common.

The varieties of strain in the back, continued Mr. Cochrane, might suitably be classified as (1) acute traumatic; (2) general postural; (3) lumbo-sacral; (4) sacro-iliac; and (5) combined pelvic joint strain. In *acute traumatic strain* the lesion represented a rupture of muscular and aponeurotic fibres with all the phenomena of acute injury. These cases were capable of getting well if early treatment of heat, massage, and recumbency, followed by graduated exercises, was enforced. The late cases were due to the persistence of the muscle spasm and to myositis. They comprised the large number of such cases which were on compensation in industry. They could not be cured by perfunctory treatment. *General postural strain* was a condition of general muscular and ligamentous fatigue without definite localisation of symptoms. It occurred in slender individuals with poor postures who required adequate support and postural re-education. In *lumbo-sacral strain* the pain was localised to the lumbo-sacral region and sciatica was a frequent symptom. One form occurred in the heavy individual with relaxed abdomen. The clinical features of *sacro-iliac strain* were quite definite. Treatment was by a suitable support and postural re-education. In resistant cases manipulation under an anæsthetic was required, and in selected cases an arthrodesis operation. By *combined pelvic joint strain* was meant that in cases of semi-sacralisation of the fifth lumbar vertebra secondary strain of the sacro-iliac joint could and did occur.

In conclusion, Mr. Cochrane said that injury of the back was often only one factor in a compensation problem, and treatment must have regard to the other factors. To make diagnosis more accurate, a routine method of careful physical examination must be employed, based upon an appreciation of the anatomy and statics concerned. The chronic cases would continue to be unsatisfactory under present conditions since they have to be treated very largely as out-patients.

Dr. FREDERICK PORTER opened a discussion on the sphygmometer in general practice, which will be continued at a later meeting.

ROYAL INSTITUTION OF GREAT BRITAIN.—Afternoon lectures of the juvenile course will be given on Tuesday, Thursday, and Saturday of next week at 3 P.M., by Prof. A. V. Hill, F.R.S. The subject of the course is Nerves and Muscles: How We Feel and Move; and the titles of the lectures are Nerves and the Messages they Carry (Dec. 28th); Muscles and How they Move (Dec. 30th); and the Heart and Some Other Muscles (Jan. 1st). The address of the Royal Institution is 21, Albemarle-street, London, W. 1.

Reviews and Notices of Books.

THE RESPIRATORY FUNCTION OF THE BLOOD.

Part I. *Lessons from High Altitudes.* By J. BARCROFT. Cambridge University Press. Pp. 207. 12*s.* 6*d.*

A REVISION of Prof. Barcroft's well-known book "The Respiratory Function of the Blood," being found impossible owing to the rapid advance of knowledge in that particular line of research, it has been decided by the author to present the subject matter in the revised form of a series of publications of which the first is entitled Lessons from High Altitudes. The book is largely coloured by the experiences of Prof. Barcroft and his colleagues in their famous expedition to Cerro de Pasco.

We learn that the first causative factor in the production of the symptoms and signs of mountain sickness is oxygen-want by the medulla—that is to say, a discrepancy between the oxygen supplied to and demanded by this tissue. The interpretation of the accelerating influence of exercise, meals, and cold on the production of this symptom-complex is thus facilitated and simplified. A comparative study of the suitability or adaptability of various geographical districts to the investigation of the physiological effects of high altitudes leads the author to the conclusion that Cerro for the time being holds the palm. And this for several reasons—namely, the possibility of rising to this height (14,200 feet) in a day, the accessibility of higher regions, the presence of all the amenities of civilisation, and lastly, though of great importance, the fact that the district is inhabited by an indigenous population. We learn that this little people—the "Cholos"—with their clubbed fingers and chests relatively broader than ours, are a race endowed with the quality of remarkable physical endurance. In spite of the race having lived for centuries, however, at this altitude, the oxygen saturation of their arterial blood was obviously low, and at no time was any evidence obtained which militated against the view that the oxygen of the mixed arterial blood was in approximate diffusion equilibrium with that of the alveolar air. At high altitudes, after acclimatisation, the oxygen-content of the arterial blood was increased for two reasons, first that the hæmoglobin-content was increased, and secondly that the oxygen dissociation curve was shifted to the left, so that for a given alveolar oxygen pressure the oxygen-content was higher than that of a blood containing the same amount of pigment and following the normal sea-level dissociation curve. The increased oxygen-content of the arterial blood leads, of course, to an increased oxygen-content of the venous blood, provided that the oxygen consumption is the same on the mountains as at sea-level. The mean oxygen pressure in the capillaries is thus raised, and this rise is probably an important factor in producing the phenomena of acclimatisation. Prof. Barcroft stresses the point that the real essence of acclimatisation is a redistribution of disadvantages over the whole body, so that the acute effects of oxygen-want, manifesting themselves in the symptomatology of mountain sickness, gradually disappear as the initial strain becomes divided between the many organic functions on which the well-being of the individual depends.

Authoritative accounts of research seldom fail to hold the attention of the reader. Here a fine imagination is curbed by rigorous experimental test, and the clarity with which problems are presented, grappled with, conquered, or left unsolved, marks this book as a classic of scientific thought and accomplishment.

X RAY DIAGNOSIS.

By MAGNUS REDDING, F.R.C.S., Senior Surgical Radiologist, Guy's Hospital. London: Cassell and Co., Ltd. 1926. Pp. 228. 21*s.*

IN this book we have an outline of radio-diagnosis—straightforward, well balanced, and well illustrated. It is reasonable in size and price and is written by a radiologist of wide experience. The whole range of radio-diagnosis is covered, and the author has avoided unduly stressing any of those special methods which have their vogue but eventually find but an unimportant place in diagnostic methods. Radiological knowledge has now become so extensive that a book of this character must perforce omit much; perhaps more than a single paragraph might have been given to such important subjects as pleurisy and gastric ulcer, even in so brief an account of chest and gastro-intestinal work as has been included. Bone work is more exhaustively discussed than any of the other sections. There are one or two small errors which will, no doubt, be corrected in the second edition, as, for instance, the statement on page 106 that the left side of the diaphragm is one and a half inches higher than the right. We doubt also if the pathology of Köhler's disease given would be generally accepted. The description of the accessory bones of the foot would be much helped by line drawings of the various ossicles.

As a text-book for students this volume will rank among the best yet published in this country, and can be warmly commended to all students of the subject. We wish it every success.

CLINICAL EXAMINATION OF THE NERVOUS SYSTEM.

Third edition. By G. H. MONRAD-KROHN, M.D. Oslo, M.R.C.P. Lond., Professor of Medicine in the Royal Frederick Hospital, Oslo. With a foreword by T. GRAINGER STEWART, M.D., F.R.C.P., Physician to the National Hospital, Queen-square, &c. London: H. K. Lewis and Co. 1926. Pp. 201. 7*s.* 6*d.*

PREVIOUS editions of this practical compendium of neurological examinational methods have been commended to the student and practitioner and its usefulness is likely to be increased by its appearance in a third issue. The elements of diagnosis naturally creep in as the book gets larger, which is all to the good. Of convenient pocket size and well illustrated, it is a vade-mecum of an acceptable kind.

THE MAYO CLINIC PAPERS.

Collected Papers of the Mayo Clinic and the Mayo Foundation. Edited by Mrs. M. H. MELLISH, H. BURTON LOGIE, M.D., and CHARLOTTE E. EIGEN MANN, B.A. Vol. XVII. (1925). London: W. B. Saunders Company, Ltd. 1926. Pp. 1078. 60*s.*

THE seventeenth volume of the Mayo Clinic papers maintains the reputation of its predecessors. It contains over 1000 pages and the variety of subjects dealt with is bewildering. Many of the contributions are given by title only and others in the form of short extracts. The general reader might have been grateful if more restraint in the reprinting of articles had been exercised; all the contributions have been already printed elsewhere, so that a very short abstract with a reference to the source would, in many instances, be adequate. A volume of a more manageable size would result, and it would contain the cream of the output of one of the most progressive clinics in the world. Such criticism savours, however, of ingratitude, for the preface claims that this result has already been attained. There could in any case be no better mirror of the progress of surgical science than the Mayo Clinic volumes. Each department of the clinic keeps itself informed of what is being done elsewhere, and every new suggestion is put to the test on a scale and with a thoroughness which cannot be matched in many clinics, at any rate in this country. The subjects dealt with include the diagnosis and treatment of gastric and duodenal ulceration, which still exercises the minds and fingers of surgeons in all countries; the functions of the liver and gall-bladder with special reference to cholecystography and operations upon jaundiced patients; ulcerative colitis, its ætiology and treatment; the treatment of patients with urinary obstruction; the functions of

the thyroid gland; the surgical treatment of disorders of the circulatory system; the relation of the spleen to purpura hæmorrhagica; and the treatment of various forms of carcinoma with radium emanations.

The scale upon which it works enables the Mayo Clinics to embody in its publications the results of the investigation and treatment of unusually large numbers of cases of any one disease. This present volume contains studies of 1000 cases of carcinoma of the prostate, of 15 verified cases of primary carcinoma of the duodenum, and of 30 cases of proved tuberculosis of the pleura.

It is obvious that a brief survey can give only an inadequate idea of the material that the Mayo Clinic volume puts at the service of its readers.

THE NEW BIOLOGY.

Essays in Popular Science. By JULIAN HUXLEY. London: Chatto and Windus. 1926. Pp. 307. With 6 plates and 20 text figures. 16*s*.

Prof. Huxley need not apologise for books like this. It is in every way desirable that the advances which have been made in experimental zoology in the last 20 years should be made available in a form tolerably easy to assimilate, on the one hand for the general educated public and on the other for those who practise applied biology in its special relations to medicine. Every medical man who has been qualified ten years or more, and has read no zoology since, might read with advantage "The Tadpole: a Study in Developmental Physiology," the longest and best chapter, and "The Frog and Biology," which is the next longest and almost as good. The other 16 essays are all readable, but they are less instructive and some of them are frankly trivial; the one headed "Why do more boy babies die than girls?" is either frivolous or an illustration of how the most modern geneticists can comfort themselves by juggling with words. In "Thomas Henry Huxley and Religion" the grandson gets out of his depth, though the pellucid stateliness of the illustrative quotations which he gives is refreshing. It would have been well if the two versions (pp. 31, 276) of the effect of nerve section on the orderly reconstitution of tendons had been concordant. But for all these criticisms the volume is to be welcomed, and we hope that Prof. Huxley will follow up this second collection with a third and a fourth as occasion arises; the more medicine can assimilate the progress of biology the more it will advance itself.

MINERVA.

Jahrbuch der gelehrten Welt. Edited by Dr. GERHARD LÜDTKE, with the assistance of Dr. FRITZ EPSTEIN. 28th issue. Berlin and Leipzig: Walter de Gruyter and Co. 1926. In three volumes. Pp. 2714. Mk.80, bound in linen.

THE twenty-eighth issue of this renowned year book appeared in May, but did not reach us until later in the year, and we have kept it awhile in daily use before comment. It is a compendious work of reference of singular accuracy. First appearing in 1891 as a Year Book of the Universities of the World, with the definite idea of strengthening the bond between the intellectual élite throughout the civilised world, it has grown year by year until it has become a guide to the seats of learning of all kinds. The 1891–92 issue contained 360 pages, about 6 inches by 4, within a single cover; the present issue consists of two volumes comprising 2362 pages, about 8 inches by 5½, with a separate index volume containing at a rough estimate 65,000 names. To take an example: the section dealing with London, England (London, Canada, has a separate entry), opens with the teaching schools, beginning with the University, of which the names of professors and readers are given, followed by details of staffs, libraries, and museums of University and King's Colleges. Four pages are allotted to the medical schools of the University, with the officers of the hospitals and the teachers in the schools set out in type so well chosen and arranged that there is no work of reference in which they are easier to find. There follows an alphabetical list of medical foundations, including the Medical Research Council, the Institutes of Hygiene and Public Health, and so forth, the information in each case having been brought up to Easter of the current year, unless an asterisk calls attention to the fact that the entries are of older date. Other faculties are dealt with in like manner, and there is a complete list of Fellows of the Royal Society, with their dates and subjects. The data for Paris, Montreal, or Tokio are as accurate as those for London, and for this edition special pains have been taken to complete the academic data for South America and Eastern Asia. We can testify from personal experience that the misprints in this vast collection of exact material are few, and the errors trifling. There are, for instance, not two Kews, one at Richmond and one near London, as the geographical index (p. 2368) would imply, and the Maudsley Hospital (p. 1108) should be spelt with a u and not with an n. Moreover, we fail to find in this, as in every other work of reference, the initials of Prof. Wieland, of Heidelberg (perhaps he has none). To mention these minutiæ is but to call attention to the wonderful accuracy of the work as a whole, which is a monument to the care and diligence of its compilers. Dr. Fritz Epstein, who has been responsible for this and the previous edition, is now retiring in favour of Dr. Friedrich Richter, the book being produced under the general editorship of Dr. Gerhard Lüdtke, to all of whom the learned world which they have so carefully indexed owes a debt of gratitude.

WINE AND THE WINE LANDS OF THE WORLD.

By FRANK HEDGES BUTLER. London: T. Fisher Unwin, Ltd. 1926. Pp. 271. 15*s*.

Mr. Frank Hedges Butler, well known in the aeronautic world, whose name is a guarantee for his intimate knowledge of wine, has written a pleasantly discursive book from which the reader can obtain a general knowledge of the wine industry, as well as much special detail, the written pages being fully supplemented by well-chosen illustrations. There is accurate information in many other books upon the wines of France, while their official classification is ancient reading to all who know anything of the subject, and here Mr. Butler's notes on the various growths follow familiar lines. But many readers will like to have his critical reasons to support their preferences, and what he terms a "glossarial essay in the natural history of wine" will be useful to them; for an exact appreciation of the language of wine is necessary when judges are attempting to arrive at accurate conclusions as to the qualities of the particular vintage or growth. Less familiar ground is covered in the discursive chapters dealing with the wines of Russia, Kashmir, North and South Africa, Australia, and the Argentine, which contain matter that will be novel to many, while amusing chapters are added dealing with drinking songs, fashion in wine, and the arrangement of a complete wine service in the elaborate menu. The author concludes with a dated record of the vintages of the twentieth century, which should assist in the making of a cellar, whether for the individual taste or for consumption in clubs and hotels.

VICTORIAN JOTTINGS FROM AN OLD COMMON PLACE BOOK.

By Sir JAMES CRICHTON-BROWNE, M.D., LL.D., F.R.S. London: Etchells and Macdonald. 1926. Pp. 344. 15*s*.

THE key-note of this work is struck by the frontispiece which its author has with happy foresight selected, for it is the portrait of himself, by "Spy," of Vanity Fair, a portrait which is, we have always thought, one of "Spy's" most happy efforts in the academic world, ranking with the drawings of Dr. George Brodrick, the Warden of Merton, and Dr. Goodford, the famous Provost of Eton.

Sir James Crichton-Browne's book is, as he prefaces, "a mere medley, atoms without cohesion or con-

cinnity," but is none the less delightful. His reminiscences begin with a charming picture of his early home in Edinburgh, the house of his grandfather, where he could pick ripe Jargonelle pears out of his bedroom window. Thereafter follow stories and episodes dealing with all sorts and conditions of men—the clergy, the services, lawyers, medical men, tradespeople, countryside folk, and lunatics—all happily remembered and almost always with some reason for their recording. It is not proposed to spoil the book for readers, and perhaps the presentation of the stories, by reproducing them, but there are one or two for which we must thank the author. There is a story related by Sir Spencer Robinson as to an answer given in an examination at Greenwich for naval lieutenants qualifying for special branches, which should not be missed. The episode forms one more instance of how little room there is for a sense of humour in the corporate proceedings of examining boards—Sir Spencer Robinson wished to pass the audacious and lively candidate, but his fellow examiners would have none of him, and no other issue could have been expected. A pleasing anecdote, again, is that which concerns the captain of a merchant ship who had occasion to enter in the log "The chief mate is very drunk to-day." On the mate expostulating, he was informed that nothing could be deleted from the log, and that the entry was a matter of fact. Some days later, the captain being on shore all day, the mate entered up the log, and among the entries put "The captain is sober to-day"—also a record of fact which could not be deleted. And the pecuniary estimate of a young woman of the advantages of education, is, in the language she would have used, "quite priceless." There are a few medical memoranda, but as a rule the author confines himself to social and political matters.

We have read the book with great pleasure, and hope that there will be issued a second set of reminiscences, and that a further edition of the present instalment will be called for and give an opportunity for more careful revision of the proofs; for we must allude to an extraordinary number of mistakes in the spelling of proper names both in the text and the index. Where the point of a story depends upon the personalities it is inconvenient that the references should be made doubtful. On p. 7 the name "Greig" should read "Gleig"; on p. 141 "Meymont" Tidy should read "Meymott" Tidy; on p. 180 "Packington" should read "Pakington"; on p. 254 G. "Broughton" R.A., should read "Boughton"; on p. 316 "Muygbridge" should read "Muybridge." On p. 126 "Cantlie" appears twice over as "Cantile." On p. 288 a very well-known line from Tennyson's beautiful song is printed as "Rose, a nurse of ninety years," thus acquainting the readers with the nurse's Christian name. It is interesting to see that this nonsensical reading has persisted for many years, for it is an old joke that a juvenile writer of hexameters translated the passage as "Rosa nomine nutrix"; according to that story the school-boy earned commendation for an ingenious variant reading, but it seems now likely that he was translating literally a printer's error. Another amusing combination of wrong punctuation and bad grammar appears on p. 300 in a learned and interesting paragraph on the Erection of Hair, where the printer has made a hash of the striking and apposite passage from Virgil. On p. 305 the author refers to the "Ballad of Miss Bayley," which he says he has not heard since he was 5 years old, when a nursemaid used to sing it to him. He will find it on p. 92 of "An Anthology of Humorous Verse," edited by Sir Theodore Cook; it begins "A captain bold of Halifax, who lived in country quarters—" the metre, rare in English, is common in Romaic folk ballads—but it continues in a manner that makes one imagine the nursemaid to have been an emancipated young lady.

A capital book, whose accomplished author, we are sure, will not resent the suggestion that in future issues slips should be remedied.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

A MEETING of the President and General Council of King Edward's Hospital Fund for London, for the purpose of awarding grants to the hospitals and convalescent homes for the present year, was held at St. James's Palace on Dec. 14th, His Royal Highness the Prince of Wales being in the chair.

The Financial Statement.

Lord Revelstoke (the hon. treasurer) said that at the November meeting the Council decided that the ordinary distribution should be maintained at £245,000, the amount to which it was increased last year. In addition, the grants during the year out of the legacies of Mr. and Mrs. Wells amounted to a further £39,750. The two distributions together, therefore, represented a total of £284,750. The ordinary distribution of £245,000 was arrived at by taking the whole of the income for the year, estimated at £236,000, and by adding to this amount the undistributed surplus of last year, which amounted to almost exactly £9000. Taking the two years together the amount distributed would be practically balanced by the total derived from the two sources indicated. It followed, therefore, that the income for 1926 was less than that for 1925 to the extent of about £18,000. This diminution was mainly due to a decrease from £19,549 to £3590 in the amount received in respect of legacies. The British Charities Association had contributed to the Fund the sum of £15,000 this year, as against £20,000 last year. On the other hand, the Fund had received this year £27,300 by way of donations as against £22,829 in 1925, the increase being mainly attributable to a munificent gift of £10,000 from Mr. Albert Searle, and to one of £7000 from an anonymous donor who had supported the Fund on more than one previous occasion. The grants of £39,750 made from the Wells legacies increased the total distributed from that source, to date, to the sum of £177,750.

League of Mercy.

Sir William Collins, in making his annual statement on behalf of the League of Mercy, said that some districts showed a falling off, but it was hoped that those showing an increase would counter-balance this. The falling off was attributed in some districts to the coal dispute, and in others to the competition of contributory schemes and to the practice of asking payment from patients. This year the British Charities Association had handed in £5000 for distribution to voluntary hospitals in almost every county in England and in Northern Ireland. He was able to recommend that the sum of £15,000 should again be handed over to the King's Fund, making a total of £398,034 contributed by the League to the King's Fund. The grand total of distribution for voluntary hospitals in London and outside by the League in 27 years was £485,368.

Grants to Hospitals and Convalescent Homes.

The Vice-Chairman of the Distribution Committee (Sir John Rose Bradford, P.R.C.P.) presented the report of the committee on the distribution to hospitals (including recovery and convalescent branches), and moved the adoption of the recommendations. The report stated that the number of hospitals applying for grants was 136, as against 133 in 1925, new applications having been received from the Hostel of St. Luke, the Ormond Maternity Home, and St. Paul's Hospital for Skin. Further progress was made during 1925 by the hospitals, taken as a whole, towards the re-establishment of their financial position. The number of hospitals showing deficits for the year had been again reduced, and, though the aggregate surplus was smaller than for the year 1924, this was due less to legacies and more to the results of successful special appeals for voluntary

contributions. The number of available beds had been increased and numerous fresh extension schemes had been undertaken. The total grants towards extensions and improvements amounted to £35,475, as against £28,925 in 1925, and that £207,525 would be distributed in grants to maintenance, as compared with £214,075 in 1925. These figures were in addition to £39,750 in grants to schemes of capital expenditure out of the special distribution of the legacies of the late Mr. and Mrs. Wells. When all the extension schemes which were now being actively promoted by the hospitals in London had been completed the number of available beds would be 1632 more than it was on Dec. 31st, 1925. The schemes that had come before the King's Fund also included the provision of improved out-patient departments, additional nurses' accommodation, and other structural work that does not add to the number of beds available for patients.

Lord Somerleyton (hon. secretary) presented the schedule containing the list of awards to hospitals (including recovery and convalescent branches) as follows :—

*List of Awards.**

	£
Acton Hospital (of which £250 on deficit on extension, in accordance with the scheme submitted to the Fund)	950
All Saints' Hospital	75
Babies' Hospital (Deptford Fund)	25
Baby Clinic Hospital (Kensington)	50
Beckenham Cottage Hospital	400
Belgrave Hospital for Children (of which £500 to deficit on new nurses' accommodation)	1,800
Blackheath and Charlton Hospital (of which £50 towards improvements)	250
Bolingbroke Hospital (of which £750 towards erection of new ward block)	2,100
Brentford Cottage Hospital (of which £500 towards rebuilding and extension on new site)	525
British Hospital for Mothers and Babies, Woolwich	500
Bromley Cottage Hospital	150
Carshalton and District Hospital (of which £100 towards scheme)	200
Central London Ophthalmic Hospital	500
Central London Throat, Nose and Ear Hospital	150
Charing Cross Hospital (of which £2,000 towards acquisition of adjoining building and its adaptation as an extension of the hospital)	6,000
Chelsea Hospital for Women (including Convalescent Home at St. Leonards)	925
Cheyne Hospital for Children (including Country Branch at St. Nicholas-at-Wade) (of which £250 to deficit on increased accommodation for artificial sunlight treatment and other improvements)	600
City of London Hospital for Diseases of the Heart and Lungs (Victoria Park) (including Convalescent Home at Saunderton) (of which £500 towards new surgical block)	4,100
City of London Maternity Hospital (of which £500 towards new nurses' accommodation)	1,500
Clapham Maternity Hospital	300
Dreadnought Hospital (Seamen's) (including Albert Dock Hospital, Hospital for Tropical Diseases, Sanatorium at Liphook, and Convalescent Home at Cudham) (of which £50 towards provision for artificial sunlight at the sanatorium at Liphook)	2,100
East End Mothers' Lying-in Home (of which £500 to deficit on acquisition of adjoining building and its adaptation for nurses' quarters)	1,100
East Ham Hospital (of which £1,000 towards rebuilding as general hospital)	1,175
East London Hospital for Children (including Convalescent Home at Bognor) (of which £250 to reduce debt)	3,240
Elizabeth Garrett Anderson Hospital (including Recovery Branch at Barnet) (of which £1,000 towards extension)	2,725
Eltham and Mottingham Cottage Hospital	25
Enfield War Memorial Hospital (of which £100 towards improved X ray accommodation)	400
Evelina Hospital	1,000
Finchley Memorial Hospital (of which £250 towards provision of casualty wards)	550
Florence Nightingale Hospital for Gentlewomen	350
Forest Hospital, Buckhurst Hill	200
French Hospital	350
General Lying-in Hospital	600
German Hospital	350
Gordon Hospital for Fistula	50
Grosvenor Hospital for Women (of which £250 towards provision of accommodation for resident medical officer and for nurses)	750
Guy's Hospital (of which £1,500 to deficit on recent improvements)	11,500
Hampstead General and North-West London Hospital (of which £200 to deficit on recent improvements)	2,700
Hanwell Cottage Hospital (of which £25 towards improvements)	75
Hendon Cottage Hospital (of which £50 towards X ray room and sterilising room)	350
Hornsey Cottage Hospital	150
Hospital for Consumption, Brompton (including Sanatorium at Frimley (of which £250 towards removal of X ray department from basement)	1,250
Hospital for Diseases of the Throat	200
Hospital for Epilepsy and Paralysis (of which £250 towards extension of in-patient department)	2,000
Hospital for Sick Children	4,000
Hospital for Women (Soho-square)	850
Hospital of St. John and St. Elizabeth	750
Hostel of St. Luke	200
Ilford Emergency Hospital (of which £1,000 towards extension)	1,400
Infants Hospital	350
Invalid and Crippled Children's Society Hospital (Canning Town) (of which £250 towards extension of out-patient department)	700
Italian Hospital	100
Jewish Maternity Home	25
Kensington, Fulham, and Chelsea General Hospital (of which £500 towards rebuilding and extension)	600
King Edward Memorial Hospital (Ealing) (of which £1,000 towards extension)	1,400
King Edward VII.'s Hospital for Officers	250
King's College Hospital	7,500
Kingston-upon-Thames Victoria Hospital	100
London Fever Hospital	500
London Homœopathic Hospital (of which £200 towards improvements to hospital)	1,700
London Hospital (including Recovery Branch at Reigate) (of which £1,000 towards improvements)	15,625
London Jewish Hospital (of which £500 towards extension, in accordance with the scheme submitted to the Fund)	750
London Lock Hospital (of which £500 to maintenance of Harrow road hospital and £100 to maintenance of Dean-street hospital, and £500 towards the building of an extension of the out-patient department at Dean-street)	1,100
London Temperance Hospital (of which £250 to reduction of debt)	2,000
Maternity Charity and District Nurses' Home (Plaistow) (to the hospital : of which £200 to deficit on rebuilding and extension)	700
Medical Mission of the Good Shepherd, Babies' Home (Hoxton)	25
Metropolitan Ear, Nose and Throat Hospital	25
Metropolitan Hospital (of which £1,500 towards new nurses' home)	5,500
Middlesex Hospital (including Convalescent Home at Clacton) (of which £2,000 towards reconstruction	9,125
Middlesex Hospital Cancer Charity	1,000
Mildmay Memorial Hospital	400
Mildmay Mission Hospital (of which £500 towards nurses' home)	1,500
Miller General Hospital for South-East London (including Convalescent Home at Bexhill) (of which £1,500 towards extension)	4,575
Mothers' Hospital of the Salvation Army (of which £250 to deficit on extension)	800
Mount Vernon Hospital (Fitzroy-square and Northwood) (of which £500 towards extension)	1,500
National Hospital, Queen-square (including Convalescent Home at Finchley)	3,250
National Hospital for Diseases of the Heart (of which £400 to deficit on extension of out-patient department)	700
Nelson Hospital (South Wimbledon) (of which £250 towards provision of maternity block)	950
Northcourt Hospital and Home for Sick Children (Hampstead) (in consideration of the fact that curable cases are admitted)	100
North Islington Infant Welfare Wards	50
Norwood and District Cottage Hospital	425
Ormond House Maternity Home	15
Paddington Green Children's Hospital (including Convalescent Home at Slough)	1,075
Passmore Edwards Hospital for Wood Green, &c.	100
Phillips Memorial Homœopathic Hospital, Bromley	20
Poplar Hospital for Accidents (including Convalescent Home at Walton-on-the-Naze) (of which £250 towards provision of children's ward)	475
Prince of Wales's General Hospital (including Convalescent Home at Nazeing) (of which £500 to reduce debt)	5,350
Princess Louise Kensington Hospital for Children (formerly Kensington Dispensary and Children's Hospital) (of which £250 towards building of new hospital)	275
Queen Charlotte's Maternity Hospital	1,500
Queen Mary's Hospital for the East End (including Convalescent Home at Theydon Bois) (of which £1,000 towards new casualty block)	4,650
Queen's Hospital for Children (including Convalescent Home at Bexhill) (of which £250 to reduce debt and £200 towards additional nurses' accommodation)	4,175
Royal Dental Hospital of London	250
Royal Eye Hospital	700
Royal Free Hospital (of which £500 to reduce debt)	5,500
Royal Hospital (Richmond)	900
Royal London Ophthalmic Hospital (of which £250 to reduce debt)	3,000

* The Distribution Committee draw attention to the fact that it must not be assumed that the reduction or absence of a grant implies dissatisfaction.

	£
Royal National Orthopædic Hospital (including Country Branch at Stanmore (of which £1,000 towards extension of country branch)	5,000
Royal Northern Hospital (including Royal Chest Branch in City-road, Recovery Branch at Southgate, and Convalescent Home at Clacton) (of which £500 to reduce debt and £250 towards improved X ray accommodation)	8,450
Royal Waterloo Hospital for Children and Women (of which £750 towards new nurses' accommodation)	3,250
Royal Westminster Ophthalmic Hospital (of which £1,000 towards removal and extension)	1,500
St. Andrew's Hospital (Dollis Hill) (of which £300 towards new nurses' home)	575
St. Bartholomew's Hospital (of which £1,000 towards new nurses' accommodation)	7,000
St. Columba's Hospital (of which £100 towards new lift)	400
St. George's Hospital (including Recovery and Convalescent Branch at Wimbledon)	7,050
St. John's Hospital (Lewisham)	1,000
St. John's Hospital (Twickenham)	100
St. John's Hospital for Diseases of the Skin	300
St. Luke's Hospital for Advanced Cases (of which £100 towards extension of nurses' accommodation)	425
St. Mark's Hospital (of which £500 towards extension)	800
St. Mary's Hospital (of which £1,000 towards extension)	6,500
St. Mary's Hospital for Women and Children (Plaistow) (of which £250 to deficit on new nurses' home)	2,000
St. Monica's Home Hospital	100
St. Paul's Hospital for Skin	25
St. Peter's Hospital for Stone (of which £250 towards extension)	600
St. Saviour's Hospital for Ladies of Limited Means (Osnaburgh-street) (of which £250 towards improvements)	375
St. Thomas's Hospital (of which £500 towards diet kitchen and extension of X ray department)	10,500
Samaritan Free Hospital for Women (including Convalescent Home at Amersham)	1,350
Santa Claus Home	75
Seamen's Hospital Society (*see* Dreadnought Hospital)	
South-Eastern Hospital for Children (Sydenham) (of which £500 to deficit on new nurses' home)	1,250
South London Hospital for Women (of which £750 towards new out-patient department)	1,750
Stoke Newington Home Hospital for Women	75
Streatham Babies' Hospital	25
University College Hospital (of which £500 to reduce debt)	8,000
Victoria Cottage Hospital (Barnet)	100
Victoria Hospital for Children (including Convalescent Home at Broadstairs)	2,700
Walthamstow, Wanstead, and Leyton Children's and General Hospital (of which £750 towards extension)	1,650
Weir Hospital, Balham	100
West End Hospital for Nervous Diseases	1,500
Western Ophthalmic Hospital	300
West London Hospital (of which £750 towards additional nurses' accommodation)	6,250
Westminster Hospital (of which £750 to reduce debt)	5,900
Willesden General Hospital	1,800
Wimbledon Hospital (of which £250 towards provision of children's ward)	650
Winifred House Invalid Children's Convalescent Hospital Home	25
Woodford Jubilee Hospital (of which £150 towards extension)	225
Woolwich and Plumstead Cottage Hospital	25
	£242,500
SPECIAL GRANT.	
Woolwich and District War Memorial Hospital Building Fund (towards provision of general hospital)	500
Total	£243,000

Lord Marshall having seconded, the motion was put and carried unanimously.

Distribution to Convalescent Homes.

Sir John Rose Bradford then presented the report of the committee on the distribution to convalescent homes not attached to particular hospitals, which stated that the number of applications eligible for consideration amounted to 44, as compared with 42 last year.

Major Harold Wernher (hon. secretary) presented the schedule containing the list of awards as follows:

	£
All Saints' Convalescent Hospital (Eastbourne)	175
All Saints' Convalescent Home (St. Leonards)	25
Baldwin Brown Convalescent Home (Herne Bay)	25
Beau Site Convalescent Home (Hastings)	25
Brentwood Convalescent Home for London Children (Brentwood)	25
Bushey and Bushey Heath Children's Convalescent Home (Bushey)	25
Children's Convalescent Home (Beaconsfield)	25
Children's Cottage Hospital (Cold Ash, Newbury) (in consideration of the fact that convalescent cases are admitted)	25
Children's Home Hospital (Barnet) (in consideration of the fact that convalescent cases are admitted)	25
Convalescent Home for Poor Children (St. Leonards)	75
Convalescent Police Seaside Home (Hove)	75
Friendly Societies' Convalescent Home (Herne Bay)	25
Home for Invalid Children (Brighton)	50
Invalid Children's Aid Association Homes—	
Brooklands Home (Worthing)	50
Clevedon Sanatorium (Broadstairs)	50
Convalescent Home for Children (Hawkenbury, Tunbridge Wells)	25
Countess Brownlow Home (near Berkhamsted)	25
Edgar Lee Home (Willesden)	50
Florence Emma Home (Dover)	25
Hamilton House (Seaford)	50
Kurandai Home (Hartfield, Sussex)	75
London and Ascot Priory Convalescent Home (Bracknell)	75
London and Brighton Female Convalescent Home (Brighton)	50
London Homœopathic Convalescent Home (Eastbourne)	25
Mental After-Care Association Homes (Fairlight)	150
Metropolitan Convalescent Institution (Bexhill, Broadstairs (Children) and Walton)	100
National Sunday School Union Convalescent Home (Clacton)	50
Ranyard Mission Convalescent Home (St. Leonards)	40
St. Andrew's Convalescent Home (Folkestone)	75
St. Andrew's Convalescent Hospital (Clewer)	50
St. John's Home (Kemp Town, Brighton)	50
St. Luke's Home (Children) (Woodley, Reading) (in consideration of the fact that convalescent cases are admitted)	25
St. Mary's Convalescent Home (Birchington (in consideration of the fact that convalescent cases are admitted)	50
St. Michael's Convalescent Home (Westgate)	50
Seaside Convalescent Hospital (Seaford)	50
Suffolk Convalescent Home (Felixstowe)	50
Sunshine Convalescent Home for Children (Felpham, Bognor)	10
Surgical Home for Boys (Banstead) (in consideration of the fact that convalescent cases are admitted)	25
Tilford Convalescent Home for Children (Farnham)	50
Victoria Home for Invalid Children (Margate) (in consideration of the fact that convalescent cases are admitted)	25
Total	£2,000

The motion, having been seconded by Dr. Louisa Garrett Anderson, was then put and carried unanimously.

On the motion of the Governor of the Bank of England (the Right Hon. Montagu C. Norman), seconded by the Chairman of the London County Council (Sir George Hume, M.P.), it was resolved that the cheques for the grants should be posted immediately.

Wells Legacies Distribution: List of Grants to December, 1926.

Sir John Rose Bradford then presented the report of the committee on the special distribution to hospitals out of the Wells legacies to date, in aid of extensions and improvements. This stated that the schemes assisted by these grants for the year 1926 would provide approximately 420 additional beds, of which 51 would be reserved for accident cases, besides any that might be so reserved at Charing Cross. As 93 accident beds were included in the schemes assisted out of the Wells legacies distributions in 1924 and 1925, and 32 in schemes provided by hospitals with funds from other sources, the total increase in accident accommodation since the publication of the report of the Ambulance Cases Disposal Committee of the King's Fund amounted to at least 176.

Major Wernher (hon. secretary) presented the schedule containing the list of awards to hospitals out of the Wells legacies for the year, in aid of extensions and improvements, as follows:—

Charing Cross Hospital.—£5000 towards scheme of extension.

East Ham Hospital.—£5000 towards rebuilding.

Elizabeth Garrett Anderson Hospital.—£2000 towards first stage of extension, increasing the number of beds from 75 to 100.

Finchley Memorial Hospital.—£500 towards new casualty wards of 8 beds, increasing the number of beds from 47 to 55.

Ilford Emergency Hospital.—£2000 towards extension, increasing the number of beds from 62 to 100.

Kensington, Fulham and Chelsea General Hospital.—£1500 towards the first stage of the rebuilding scheme, providing 44 beds instead of the present 19.

Mildmay Mission Hospital.—£500 towards additional nurses' accommodation, new X ray department and operating theatre.

Paddington Green Children's Hospital.—£2000 towards extension, increasing the number of beds from 46 to 92.

Queen Mary's Hospital for the East End.—£5000 towards new casualty block, increasing the number of beds at the hospital from 160 to 184.

Royal London Ophthalmic Hospital.—£500 towards additional nurses' accommodation, enabling the number of available beds to be increased from 120 to 150.

St. Mark's Hospital.—£500 towards extension, increasing the number of beds from 54 to 65.

St. Mary's Hospital, Paddington.—£4000 towards extension, increasing the number of beds from 290 to 340.

South London Hospital for Women.—£2000 towards the provision of block containing new out-patient department and nurses' quarters.

University College Hospital.—£250 towards provision of four casualty beds.

Victoria Hospital for Children.—£500 towards extension of light treatment department; to be the last £500 to render the extension free of debt.

Walthamstow, Wanstead and Leyton Children's and General Hospital.—£1000 towards extension.

Wembley Hospital.—£2000 towards erection of a general hospital of 24 beds, with casualty department.

West London Hospital.—£500 towards new casualty department and additional accommodation for nurses required by the opening of recent extensions, including male and female accident wards.

Woolwich and District War Memorial Hospital.— £5000 towards erection of general hospital.

Lady Ampthill having seconded, the motion was put and carried.

Pensions for Hospital Officers and Nurses.

The Chairman of the Management Committee (the Earl of Donoughmore) presented a report of the committee on the scheme of pensions for hospital officers and nurses, as follows:—

It stated that at the annual meeting of the President and General Council in May last the Management Committee reported on the scheme of pensions for hospital officers and for nurses. The scheme itself had been described in a memorandum which was drawn up in 1925 by a conference of representatives of the British Hospitals Association, the Incorporated Association of Hospital Officers, and the College of Nursing, with the King's Fund as conveners, and was circulated to the hospitals in London and the provinces for their consideration, and for expressions of opinion and suggestions. A Provisional Council, with Sir Edward Penton, K.B.E., as chairman, was now responsible for the scheme, and at the present moment 86 hospitals in London had joined, representing 11,448 beds out of a total of about 14,500. A circular had been sent out by the Provisional Council to hospitals outside London, notifying them of the progress made since the issue of the draft scheme in November, 1925, giving a list of the kinds of institution eligible to join, and describing the proposed arrangements with insurance companies. The scheme applied to nurses not only in hospital service, but in all branches of the profession for which provision was not otherwise made.

Remarks by the Prince of Wales.

His Royal Highness the Prince of Wales then read the following gracious message from the King: "The King is glad to learn that the Fund has been able to maintain the same distribution as last year, though he realises that this has only been possible through the timely help of two or three large donations. His Majesty has much at heart the objects and activities of the Fund, which he earnestly trusts may continue to receive the generous support of the public, and thus be enabled to fulfil the demands made upon its resources, due to the ever-increasing work of the London hospitals." Continuing, he said that last year they raised the total from £235,000 to £245,000, and in the end had £9000 in hand for future contingencies. This year they were £9000 short. So, by using last year's surplus, they were just able to keep the ordinary distribution at £245,000. If the £39,750 special grants out of the Wells estates were added the grand total would be £284,750. This surplus of £9000 last year was due to legacies, which were always liable to fluctuations. This year they are very much smaller than usual. In the other items of income the receipts had been well kept up. The British Charities Association have kindly entrusted the Fund with £15,000 for hospitals in London—not quite so much as last year, but equal to 1924. Donations had increased—£27,000 as against £22,000. They included the very welcome gifts of £10,000 from Mr. Albert Searle, £7000 from one anonymous donor, and £1500 from another. These gifts had saved the situation.

The Financial Position of Hospitals.

With regard to the financial position of hospitals, there were in 1925 more surpluses and fewer deficits than in any year since the war. Voluntary gifts came to more, and patients' contributions went up; the amount collected by the hospitals for building schemes increased, and their receipts of all kinds during the year reached a colossal total. These figures were all in the King's Fund Statistical Report: voluntary gifts, £98,000 up; patients' contributions, £74,000 up; building receipts increased by £364,000; total receipts of all kinds for the year, £3,887,000. Yet, in spite of all this, said His Royal Highness, the hospitals wanted from the King's Fund distribution just as much, or even more, the reason being that their work was growing quite as fast as their income. More beds had been opened, and more still were being provided. It was quite a mistake to suppose that the voluntary hospital system was incapable of expanding. Present schemes would add 1600 beds to those that were open a year ago. The Fund was, therefore, asked to help, both in maintaining the additional wards that are open and in building those that were being provided. The Wells bequests had helped to add 1000 beds; to increase substantially the provision for dealing with accidents; and to meet the needs of newly populated areas in outer London. To meet fresh needs, the King's Fund had extended its boundaries and relaxed its rules about new hospitals, and was thus able to assist these districts both with money and, if they so desired, with advice. As a further sign of progress in hospital finance, he welcomed the announcement that the income of the Hospital Savings Association had already reached £150,000 a year, and he congratulated all concerned.

The meeting closed with the usual votes of thanks.

On the same day His Royal Highness presided over the annual meeting of the League of Mercy.

METROPOLITAN HOSPITAL SUNDAY FUND.

Sir Charles Wakefield, in the absence of the Lord Mayor of London, presided at the annual meeting of this Fund, when it was stated that the year's collections—namely, £87,049—showed a drop of £7792 on last year's total. Hospital Sunday for 1927 was fixed for June 19th.

UNIVERSITY OF LEEDS.—Sir Berkeley Moynihan has resigned from the Chair of Surgery on his retirement from the full staff of the Leeds General Infirmary. At a meeting of the University Council held on Dec. 15th a resolution was passed expressing regret at his decision and appreciation of his services.—Miss D. M. B. Gross, M.B., has been appointed part-time Assistant in Experimental Pathology and Cancer Research.

DAVOS SCIENTIFIC SPORT WEEK, JAN. 2ND TO 10TH, 1927.—During the first ten days of the New Year visitors to the Davos valley are invited to combine sport with instruction, and among those announced to give scientific lectures are Prof. Abderhalden (Halle), Dr. Diem (Berlin), General Secretary of the German National Committee for Physical Culture, Prof. Hellpach (Heidelberg), Prof. His (Berlin), Prof. Hill (London), Dr. Knoll (Arosa), President of the Swiss Medical Sport Commission, Prof. Mallwitz (Berlin), Docent Dr. Matthias (Munich Zuoz), Dr. Munck (Denmark), and Prof. Stähelin (Basle), who will between them cover the physiological and social-hygienic significance of sport, its hygiene and history, its value as a means of education, and the conditions proper to its use.

THE LANCET.

LONDON: SATURDAY, DECEMBER 25, 1926.

1926.

THE time has long gone by since any attempt could be made to recapitulate at the end of the year the progress of medicine in all its provinces in such a way as to indicate the various steps forward that had been taken during such a period. The range of medical interests is now so large, and the subdivisions so numerous, that to deal in any summary way with scientific, professional, or public advances, as they presented themselves through twelve months, would result in an outline so bare as to be useless. But it may be possible to look back over a year at its closing and to indicate what appear as the salient lessons, so that something may be learned from the events.

In the development of service rendered by medicine to the public the fact has emerged more clearly than ever during 1926 that, while the creation of special organisations of various sorts in the realm of preventive medicine has produced a new general order of things, the individual practitioner, who has the whole domiciliary care of the population in his charge, remains in the first line of defence against disease. The point was well made by Sir GEORGE NEWMAN at the Annual Oration of the Hunterian Society early in the year, when he took for his subject the part played in the evolution of preventive medicine by the private practitioner, and was able to show that hygienic prophylaxis, whose principles were laid down throughout the eighteenth and nineteenth centuries by the enterprise and wisdom of individual doctors, now, and in face of the various special activities created for the purpose, owes its inspiration and depends for its primary action upon the private practitioner. A large proportion of the medical men who serve local education and sanitary authorities are still in private practice; the Poor-law Medical Service is staffed by private practitioners almost entirely; the same can be said of the Post Office Medical Service, while the duties arising out of the National Insurance Acts fall in overwhelming measure upon the same body of men, who form three-quarters of the constituency. All this adds great weight to the evidence submitted to the Royal Commission on Local Government by the British Medical Association, in whose memorandum the need for unification of local health administration is brought out, as well as the desirability of a radical revision of the local areas in accordance with which the existing work is done. It has been pointed out in our columns that a large extension of the county borough system would go a long way towards instituting the necessary reforms, for hand-in-hand with this extension there would be a general recognition of the place that the large institution must play in modern curative medicine, while such institutions, when provided, would form exactly the foci that are needed for a general plan of rearrangement. In other matters than health the old areas are being altered in deference to the shifting of populations, the rise of urban aggregations, and the developing facilities for transport; and during the past year these facts have become increasingly plain to the public, while the general body of the medical profession is better prepared than it ever has been to accept the fuller responsibilities implied and to make use of the opportunities with which they would thus be provided. And once again, with regard to the pattern which such development might take, we refer our readers to the document which the Consultative Council on the Medical and Allied Services presented to Dr. ADDISON, the first Minister of Health, some six years ago. The Dawson Report was an able sketch of the possible organisation of health administration in England upon a group system, in which great care had been taken to keep medical practice at the periphery of the various areas in touch, first with the general practitioners of that area, and, secondly, with the consultant and specialist branches of the profession and the institutional machinery, thus affording to the whole community that real supervision of communal and individual welfare that was promised by the National Health Insurance Scheme.

There is a general awakening of public intelligence to the necessity for an enhanced order in the administration of medical service, and this fact has provided a really hopeful note for the medical profession during the past year of social trial, which has brought with it special anxieties for medicine; and it would have been pleasant to end on this note. But to do so would be to disregard the mass of information which has been supplied during the period by medical officers of health from centres of widely differing kinds, to the effect that housing conditions in the country still remain deplorable. There is no need to insist—so obvious is it—that in the domiciliary practice of the profession the public possesses alike its greatest alleviation of misery and readiest chances of prophylaxis; by so much is it a tragedy that the prevailing domicile should remain unsuited alike for the care of the sick or the prevention of sickness. It would be quite unfair to forget either the great improvements that have taken place recently or the extensive schemes that should soon have a like outcome; but there is need to increase the pace, and only a wider appreciation by the public of this need will furnish the required impetus. There are too many homes in this country to-day which we should be ashamed to submit to the scrutiny of even so broadly sympathetic a guest as Old Father Christmas.

RENAL TUBERCULOSIS.

THE treatment of unilateral renal tuberculosis by nephrectomy may justly be regarded as one of the triumphs of surgery. The last weeks or months of a patient afflicted with this disease, when it runs its course without intervention, are usually pitiable in the extreme. Racked with constantly recurring and painful contractions of the bladder, exhausted from want of sleep, poisoned by the tuberculo-toxin, death becomes a welcome liberator. It is no wonder that urologists, profoundly impressed by the contemplation of this gloomy picture of the disease, have strenuously advocated the necessity for early surgical treatment as the only hope for the unfortunate

victim. As a result there has arisen the belief that without it a rapid downward course is inevitable. While this is in general true, and while it has never been demonstrated that there ever occurs a complete eradication of the disease in a pathological sense, it is true to say that occasionally the disease becomes localised and shut off from the body by tissue reaction so completely that virtually it amounts to a cure. Clinically and subjectively the patient regains his health.

Mr. H. P. WINSBURY WHITE elsewhere in this issue gives an account of what is known as closed renal tuberculosis, and reports four cases. One of these is very remarkable, as it was only discovered, after death by accident, in a policeman who had performed all his onerous duties and lived his life without any urinary complaint at all. Such complete silence of renal tuberculosis is rare. Usually there have been urinary symptoms at some stage, but the ureter becoming impervious at its upper extremity, they disappear entirely, the kidney remaining as a pyonephrosis or becoming destroyed by a process of fibrosis which effectively segregates the tuberculous nidus from the rest of the body. At a recent meeting of the Royal Academy of Medicine in Ireland Prof. ANDREW FULLERTON introduced a discussion upon the tuberculous kidney by giving his experience in 150 cases. He declared that the presence of tubercle bacilli in the urine is not always conclusive evidence of a tuberculous kidney, for they may have come from a primary focus in the prostate or seminal vesicles. Cystoscopy is always required, but is sometimes accompanied by great risk, and indeed has been followed by death. When it is impossible to get the required information by cystoscopy, Mr. FULLERTON exposes the ureters in the iliac region, and by this means obtains samples of urine coming from the kidneys. He has performed 71 nephrectomies for the disease, with five deaths. He, too, described a series of cases illustrating Nature's method of cure. Mr. SETON PRINGLE, taking part in the same discussion, emphasised the fact that even with a bilateral infection the outlook for the patient is not quite hopeless. One such patient is well 15 years after the bilateral nature of the infection was established by cystoscopy, a result he attributed to tuberculin treatment, of which he is a strong advocate. So impressed has he been with tuberculin treatment that, when nephrectomy is contra-indicated, he looks upon it as an invaluable substitute for operation. From it can be confidently expected improvement, and possibly even cure. Sir WILLIAM WHEELER was able also to subscribe to the statement that bilateral disease is consistent with apparent health for a number of years. Sir WILLIAM TAYLOR described a similar 15-year-old cure with tuberculin in a case of bilateral disease.

In this country, however, the general opinion seems to be that tuberculin, whilst of use in combating infection of the epididymis, bladder, or prostate, is useless in the management of the tuberculous kidney. This is certainly too extreme a standpoint to assume, for cures under a tuberculin régime have occurred beyond doubt. Whilst it remains true that the best hope—and it is a considerable one— for a return to complete health lies in a nephrectomy, provided always the disease is unilateral, nevertheless when this ideal treatment cannot be carried out, the opposite kidney being suspect, the future for the patient is not necessarily altogether bad. He may overcome his disease by walling it off with a layer of dense connective tissue and return to apparent health. He will be assisted in this process by open-air therapy, rest, and the judicious use of tuberculin.

LOSS OF MEMORY.

JANET'S theory of dissociation, though now somewhat neglected in favour of the more dynamic theory of the unconscious, conveniently gathers under one conception a series of phenomena ranging from incidents of every-day life to hysterical anæsthesia, or double personality. In our waking moments there is present a stream of mental processes of which we are fully aware, but there may be subsidiary streams of which our awareness is less distinct. The reader of an interesting book, for example, may be dimly conscious of a feeling of discomfort that leads him to alter his position without his directing much attention to the feeling or the resultant movement. He may, indeed, claim to be quite unaware of them, and such a shutting-off of awareness may be carried to a pathological degree; so in hysterical anæsthesia the sensations arising from the anæsthetic area are, as JANET has shown, really perceived by the patient in a way that can best be understood by postulating a consciousness quite distinct from the ordinary stream. In these cases the streams of consciousness are simultaneously present—parallel, as it were; but an extension of the theory allows us to picture a dissociation of the continuity of consciousness by the irruption of a stream of thoughts, with their associated behaviour, apparently alien to the ordinary life of the subject. In "A Tale of Two Cities," the story of Dr. Manette (which indicates that DICKENS had a knowledge of abnormal psychology) gives an example of such a dissociation or change of personality, in which the cause, known to the reader, is hidden from the subject because of the abrupt break in consciousness. Dissociation is presumed to occur in somnambulisms, hysterical fugues, automatic writing, spiritualist trances, and cases of double personality. Amongst text-book examples of the latter is an account of a clergyman who disappeared from his ordinary circle, wandering away in an altered state of consciousness, and returning to his normal consciousness to find himself in business as a confectioner. The descriptions of some cases raise the suspicion that the splitting of the personality had been encouraged by the methods of the investigator, and in this connexion it may be noted that psycho-analysts have been charged with neglecting this corner of abnormal psychology, a charge which they meet by declaring that their methods prevent such splitting of the personality and hence deprive them of the opportunity of studying its course.

From one aspect, and the obvious one, a hysterical fugue, or change of personality, appears as a loss of memory. Such a loss was common in the minor psychoses of war, and the shell-shocked soldier who had lost his memory was, from another point of view, in a state of dissociated consciousness. The distinction between the suppression of memories and a dissociation of consciousness is, indeed, not always easy in theory or important in practice. The suppressed memories go to make up the dissociated stream if a fugue occurs or may, in the same patient, express themselves by symptoms which intrude into the stream whilst normal consciousness is active. Hysterical fugues as seen in war cases could often be recognised as states in which the intruding stream was made up of suppressed memories, and when, after the fugue, suitable technique succeeded in bringing these into full consciousness the result could be described either as revival of memories or reassociation of a divided consciousness. From another aspect, as hinted above, the fugue may be, like some other hysterical symptoms, the result of suggestion, and the

number of cases recently reported reminds us that hysterical symptoms can appear in epidemic form. Moreover, being a hysteria, the condition is certain to be complicated by the possibility of malingering, and in war cases the sufferers from a pathological amnesia were occasionally in serious danger, from which they were extricated only by the intervention of someone who could recognise the true condition. On the other hand, a claim of loss of memory is often an obvious attempt to escape obloquy or punishment. Since in order to understand hysterical conditions it is necessary to understand the mental processes which underlie the alterations in behaviour, and since for many people it is difficult to conceive mental processes as taking place without the person concerned being aware of them, there is a tendency either to accept fugues or doublings of personality as unquestionable, if mysterious, happenings, or to condemn them as deliberate fraud. Judgment is confused by the recognition of a purpose behind the hysteria. No satisfied and happy person is hysterical, and the symptom may be both a reaction against the surroundings and a means of avoiding or influencing them. If we seek for the *why* of a hysteria we find it not only in memories, but in motives which are not admitted to consciousness and dealt with in accordance with the needs of the situation; hence the presence of motive must not be taken as proof of the witting exercise of volition. In any case involving the question of a dissociation of personality no judgment is acceptable without personal investigation guided both by experience and a knowledge of the possibilities outlined in modern theories of psychopathology.

SCARLATINAL INFECTION OF BOOKS.

AT a recent monthly meeting of the Dunfermline District Committee the Chairman of the fever hospital, Major C. W. L. Ross, complained of the recent increased demand on beds for scarlatinal cases, which he was inclined to attribute, in part at least, to the laxity of the school authority in the matter of infected books. Several cases had been brought to his personal knowledge of children being kept at home because they were suffering from scarlet fever and having their books sent to school so that the lessons for the following day might be worked on them. In reply to Lord Elgin, who asked how the books could be disinfected and what action the health authority could take in regard to them, Dr. A. D. Campbell gave it as his opinion that it was impossible thoroughly to disinfect these books, and, when he had asked the education authority to destroy them, the reply was that they were too valuable. The Chairman of the committee said there seemed to be some doubt where the fault lay, and suggested a reference to the Board of Health for a ruling in the matter. Such ruling would, we believe, require some further investigation before it could be given. When the Society of Medical Officers of Health last discussed the spread of infection by books, there was no certain information before it that infection was ever carried through books, and, apart from virulent small-pox, the chance of infection was regarded as extremely small, if not negligible. It is known that the streptococcus of scarlet fever will only survive drying for a short time, and it is not necessarily virulent even if found alive outside the body. Dr. J. E. McCartney suggested in our columns not long ago that it would be possible to ascertain by investigation the period of survival of the streptococcus in infected books and the length of time the organism is viable under such conditions. In view of such discussions as that at Dunfermline and the important administrative questions which they raise, it seems a pity that this investigation has not yet been made.

Annotations.

"Ne quid nimis."

STILLBIRTH AND NEONATAL DEATH.

EVIDENCE is accumulating which suggests that stillbirth is avoidable in at least half the cases. The first important work done in this country on the cause of natal death in infants was published by Eardley Holland in 1922. The fœtus may be either macerated or fresh, according to whether it was dead or alive at the beginning of labour, and many investigators have shown that only about 20 per cent. of stillborn fœtuses are macerated, the remaining 80 per cent. dying during the process of labour or very shortly afterwards. The distinction is useful since, generally speaking, maceration of the fœtus denotes disease of the mother, syphilis and the toxæmias of pregnancy accounting for most intra-uterine deaths leading to maceration. This shows that syphilis—contrary to belief still current—causes only about 12 to 15 per cent. of all stillbirths. The great majority of natal deaths occur during the process of labour, the actual cause of death being either an intracranial injury or asphyxia. In a recent report, summarised on p. 1337 of this issue, Mr. Eardley Holland and Dr. J. Lane-Claypon record a survey of 1673 cases of stillbirths from various sources, their object being to assess the ætiological factors. The work has been rendered difficult and in many instances inconclusive by lack of essential information, but the findings are comparable to those of other investigators. They state that a certain number of unavoidable deaths are due to deformity of the fœtus; others—such as those following accidental antepartum hæmorrhage—cannot be prevented in the present state of knowledge. The majority, however, are caused by a failure at some point of the obstetric service. Many die because the mother is not properly supervised during pregnancy; maternal disease is not diagnosed while it can still be treated, and there is failure to diagnose pelvic contraction or malpresentation before the onset of labour. Some deaths are the result of failure of the patient to call the attendant sufficiently early in labour; whilst others are caused by bad obstetrics and particularly by the application of forceps in unsuitable cases or at the wrong time. To reduce the number of stillbirths and neonatal deaths the first essential is education of the public on the need for antenatal supervision, as it is wholly unsatisfactory to provide skilful obstetricians for the management of labour if the patients do not submit to supervision during pregnancy. Good antenatal work can lower the incidence of stillbirth (macerated fœtus) and can almost banish neonatal death if it is worked in conjunction with an efficient labour service. Its benefits, however, may be partly lost if the labour service is ineffectual, and there is still room for considerable improvement in this branch. It is unfortunate that Mr. Holland and Dr. Lane-Claypon have been unable to give any details as to the mortality and morbidity of mothers whose children are born dead, for there can be no doubt that if the fœtus is injured severely enough to cause its death the mother is likely to be injured at the same time, so that anything which makes for the reduction of obstetric interference is likely not only to reduce the fœtal but the maternal mortality at labour. The rates of stillbirth and neonatal death form a useful index of the efficiency of the maternity service as a whole. A strong case can be made out for the notification of such births and deaths, and although there are technical difficulties, they are not greater than those which arise in the notification of puerperal pyrexia.

THE ÆTIOLOGY OF MONGOLISM.

ABOUT a year ago the Section of Psychiatry of the Royal Society of Medicine met to discuss the problem of the Mongol,[1] but their combined efforts threw no light whatever on the cause of the phenomenon nor even on its true nature. The picture is much too common and well-defined to be the accidental result of a number of separate causes, and it is a reproach to pathological science that the explanation should still be unknown. Dr. A. B. Marfan, in a comprehensive summary published in the *Presse Médicale* of Nov. 3rd, deals with the three theories which command the most attention. The first is that of W. J. Langdon-Down, who has suggested that Mongolism is an anomaly of reversion to a remote ancestral type. The standing argument against this view is that, if Mongols are really throw-backs to Mongolian ancestors, they ought to be physically and mentally as fit as normal Chinese or Japanese, whereas, in fact, every one of their characteristics marks them as "half-baked." F. G. Crookshank points out a number of features which he says are characteristic of the Mongolian race and the Mongolian imbecile alike—the short, thick-set limbs; the tendency to a relative diminution in the size of the arms and thighs, as in achondroplasia; the tendency of the two lower cutaneous folds of the palms to join into one, as in certain monkeys; the fissured tongue; and many others. These may be characteristic of the Mongolian race, says Dr. Marfan, but they are certainly not uniformly characteristic of the Mongolian imbecile; some of them, moreover, are not racial characteristics but pathological stigmata. The second theory, expounded in this country by G. E. Shuttleworth and in France by Jules Comby, sees the cause in a kind of accidental impairment of the reproductive cells, a result of debility in either parent, but especially in the mother. Thus the possible causes of the condition are legion; any intoxication, infection, or injury suffered during gestation may be responsible for the change. The exponents of the theory, however, lay particular stress on the importance of unregulated emotion and repeated pregnancy in the mother. Mongols are generally, they say, the children of women who have experienced severe mental pain, fear, or disappointment during pregnancy, or who have been exhausted by many births. The chief objection to this opinion is, again, that it does not altogether fit the facts. Such causes may often predispose to abnormality, but it is difficult to regard them as essentials, for innumerable women who are the slaves of their emotions do not produce Mongols, and not a few Mongols are the offspring of mothers whose habits and environment are irreproachable. The third theory is that Mongolism is due to congenital syphilis. Those who support it advance the arguments that careful scrutiny of the family history and examination of the patient will show the existence of the infection or its stigmata in half the cases. In most of the other half they find good presumptive evidence that a syphilitic taint has been inherited from an ancestor two generations back.

Protagonists of the various theories of Mongolism may take courage from the undoubted fact that all the predisposing causes have been met with in some cases. It is, indeed, very probable that in many instances more than one predisposing condition is present. The last two children of a syphilitic mother known to us are Mongols, though the other children are normal, one being sufficiently bright to hold a scholarship. All are Wassermann-negative. The mother's infection is of long duration, and before the last two births she was worn out by poverty, worry, and repeated childbirth, while during the earlier pregnancy she underwent an emergency operation for twisted ovarian cyst. Which of the three factors—endocrine disturbance, exhaustion, or syphilitic taint—is to be held responsible in this case? Dr. Marfan, who himself inclines to the syphilis theory, points out that a number of signs exhibited by many Mongols in the first six months of life, the so-called scrotal tongue and malformations of the heart and adenoids for example, are strongly indicative of hereditary syphilis. This view is supported by the work of Babonneix, who states that post-mortem examination of a Mongol's brain shows lesions of the meninges and vessels that strongly suggest syphilis. As these lesions occur before birth and are responsible for the cortical hypoplasia that is an invariable feature of Mongolism, it is not to be expected that specific treatment would have much effect on them. The hypothesis that Mongolism can be due to syphilis in a more or less remote ancestor, as well as in a parent, is certainly ingenious. Taking into account the high incidence of the disease in the eighteenth century, when sexual morals were at a low ebb, it is argued that few families nowadays, however respectable, can claim that their line of descent is absolutely free from it. The taint is doubtless modified and attenuated, says Dr. Marfan, but is nevertheless still capable of causing harm. Attacking the endocrine glands at the outset of their growth, it inhibits their efficiency according to a more or less regular plan—and the result is the Mongol, whose all-round shortcomings are fairly attributable, considering the pathological evidence, to this cause. M. Jansen's theory of abnormal amniotic tension is consistent with this supposition, but unfortunately, although autopsies generally show a deficiency in one or more glands, not only are different glands affected in different cases but there is no regularity in the nature of the lesions.

OXYGEN ADMINISTRATION.

IN a paper read before the Therapeutic Section of the Royal Society of Medicine on Dec. 14th Dr. R. Hilton compared the oxygen in the alveolar air after its administration by the following methods: 1. Large glass funnel held 10 cm. away from the mouth. 2. Large glass funnel held in close contact with the bridge of the nose and under the chin. 3. Large glass funnel, the funnel being shaped to the face. 4. Nasal catheter, with its tip in the nasopharynx, and with one hole near the end. 5. Face-mask provided with inspiratory and expiratory valves, connected so as to supply oxygen only. Oxygen was given at rates varying from one to nine litres a minute by funnel or catheter. The figures were obtained from a normal subject, for the measure of success of any method of giving oxygen for the relief of anoxæmia must depend on estimations of the oxygen saturation of the arterial blood, and repeated arterial punctures, although safe, are not desirable in a sick man. The first essential step in the carriage of oxygen from the exterior to the blood can be examined easily by analysis of the alveolar air; the second step—namely, its further transference to the blood—cannot succeed if the first step fails. Dr. Hilton's findings appear to be definite and consistent. In the first place, they show convincingly that a glass funnel held 10 cm. from the mouth has no effect whatever on the oxygen in the lungs, even with high rates of flow. This is a conclusion, as one of the speakers remarked in discussing the paper, at which many clinicians have already arrived by their own observations. When the funnel is held in close contact with the face, however, even the lower rates of flow cause a definite rise to alveolar oxygen. Thus, the original pressure while breathing air (100 mm., i.e., 14 per cent.) was doubled with an oxygen flow of three litres per minute. With a flow of seven and a half litres per minute 350 mm.—i.e., 50 per cent.—was reached. The nasal catheter gave similar figures at low rates, but even at three litres per minute caused discomfort, and above four was not tolerated. Evidence was given to show that even the lower rates of flow had a definite effect in anoxæmia. The Haldane mask and bag, and its modification by Gilchrist and Davies, was found to be considerably more efficient than the funnel method, while the highest figures of all (over 90 per cent. oxygen in alveolar air) were obtained with the two-valved face-

mask. Owing to the intolerance of dyspnœic patients for a mask over the nose and mouth, Dr. Hilton was led to try administration by means of a mouthpiece fitted with valves, the nose not being covered. Oxygen is thus taken in by the mouth and air by the nose. This method, more readily tolerated by the patient, gave with a total ventilation of six litres per minute over 350 mm. oxygen pressure—i.e., 50 per cent—in the alveolar air.

EPILEPSY.

IN his Presidential Address [1] delivered before the Psychiatric Section of the Royal Society of Medicine on Dec. 14th, Dr. Aldren Turner referred to recent work on epilepsy and stated that, although such work had thrown new light upon this disease, it could not be claimed that the secret of epilepsy was yet revealed. He referred to the broadening of the basis of the disease and the inclusion within its ambit of disturbed states of consciousness of longer duration, which may be regarded as "equivalents" of the classical epileptic seizure. It was one of the features of epilepsy that the characteristic disturbance of consciousness was observed in association with different fundamental causes, and there was reason to believe that three special varieties—the organic, the toxi-infective or metabolic, and the psychogenic groups—could be taken out of the mass of undetermined epilepsy or "epilepsy of unknown origin." After referring to the association of epileptic fits as a symptom of cerebral tumours and in penetrating wounds of the head, he discussed briefly the circumstances attending the initiation of the "grand mal" and reviewed the doctrine that vascular spasm and cortical anæmia were the primal cause of the seizure. A view had been expressed, and had found some support, that in consequence of a local cerebral lesion, which was envisaged in epilepsy, a toxin was evolved which acted as an irritant upon the cerebral blood-vessels and caused a sudden, local, and spreading anæmia of the cortex. But what would explain a periodic local toxæmia arising unexpectedly in seeming good health and often persisting throughout a lifetime? On the other hand, a proposition had been put forward that the phenomena of epilepsy may be explained by the presence of toxic agents circulating in the blood and acting upon the cerebral blood-vessels, these agents arising from defective carbohydrate metabolism or adrenal overaction in emotional distress.

There was, said Dr. Turner, considerable clinical evidence in favour of a toxi-infective or metabolic group of epilepsies, but satisfactory biochemical support of this view was so far not available, although interesting and suggestive work was being carried out on this aspect of the disease. Of this character might be mentioned attacks of serial epilepsy and the status epilepticus, fits ensuing during or within a brief interval of the exanthemata and other infective disorders; possibly also the epilepsies arising de novo in, or aggravated by, pregnancy, lactation, and the puerperium. In Dr. Turner's view a quite unproven degree of importance had been attached by some writers to a relation between epilepsy and disturbance of endocrine function, although there was evidence of an association between pituitary tumours and epilepsy, and cases have been observed in which, from other evidence, it was probable that the pituitary glandular balance was impaired. In his experience, therapeutic measures based on endocrine deficiency had been attended by negative results. He discussed at some length the interesting question of epilepsy of psychogenic origin and referred to the great difficulty in distinguishing clinically between hysterical and epileptic types of fit-reaction in many cases, especially when the determining influence lay in some emotional cause such as shock, fright, or anxiety. He referred to the views of Rows and Bond, who regarded even the major epileptic fit as mainly the result of a disturbance of consciousness produced through memories and the emotions associated with them. But it was difficult to believe that even an intensified emotion by itself could give rise to so dramatic a crisis as the "grand mal," which in some cases might threaten even life itself. Though psychotherapy and the psychoanalytic method had been employed now for some years in the treatment of epilepsy, the beneficent effect anticipated by its advocates had not been realised. The relation between emotional distress, hysteria, and epilepsy was, however, a close one, and it was now accepted that certain individuals exhibit seizures clinically indistinguishable from epilepsy in situations of a purely psychical kind.

The "epileptic personality" described by Pierce Clark was considered by Dr. Turner to be a rare form of mental make-up in this class of patient. Ordinarily the young potential epileptic did not differ in temperament from other young persons. The nature of the disease, however, led, in course of time, to anxiety and apprehension, and the final mental condition was often one which showed some crippling of the mental faculties and a tendency towards asocial habits. This was not necessarily permanent if the fits could be arrested. After the elimination of the groups just referred to a mass of epilepsy remained, to which a social problem was attached owing to the number of cases requiring supervision in special institutions. Much of this epilepsy was of unknown origin and included the common variety of the disease arising in later childhood, puberty, and adolescence. In the study of epilepsy many clinical features of interest arose and reference was made to a few of them, such as the relative frequency of the disease in only children, the onset of the disease during periods of rapid physical growth and development, the occurrence of a few fits temporarily during some period of adult life, the occasional onset of the major seizures with the coming on of arterio-sclerosis in later life, the relation of epilepsy to sleep, dreams, and nightmares, to migraine and periodic headache, and to nocturnal enuresis and infantile convulsions. On the question of inheritance in epilepsy, Dr. Turner said there had been a tendency during recent years to belittle its influence as a predisposing factor in the disease. But it was impossible to survey the family history of any large number of epileptics without obtaining direct evidence of this in a substantial percentage of cases—about 33 per cent. according to his investigations. It was even possible to admit what might be called a "familial" group of epileptics. What the cause of the disease was in other cases was, said Dr. Turner, an unsolved problem, although various conjectural possibilities had been put forward, such as an infective disorder, an intoxication or local disease of the germ-forming organs. The facts of epilepsy, however, made it apparent that a large number of human beings had some defect, which was either inborn or acquired during or after intra-uterine life.

[1] The address will appear in full in an early number of the Journal of Neurology and Psychopathology.

THE SEYMOUR PLAN.

Dr. M. M. Seymour, Deputy Minister of Public Health for Saskatchewan, in his presidential address to the annual conference of State and provincial health authorities of North America last May, put forward the proposition that much sickness and death is still caused by diphtheria, small-pox, and typhoid, that science has placed effectual preventive agents in our hands, and that, by arousing the interest of the public, it is now possible by a united effort to wipe these diseases off our list. This implies, he says, a continent-wide attack, by means of toxoids and immunising vaccines. Dr. Seymour's proposal has been enthusiastically endorsed by the American Health Association and by the Canadian Medical Association, whose *Journal* devoted a leading article to it recently. Steps are already being taken in several districts to arouse and educate the public through the press, the clergy, and the teaching profession for the campaign. The question arises as to whether a similar campaign would be beneficial in this country. Possibly different diseases might be selected. Typhoid, for example, is becoming

extinct, and its complete eradication is chiefly a matter of the better control of shell-fish and of carriers. Most of the cases which occur now are of the milder paratyphoid type, the origin of which is frequently obscure, although imported foods from the East have fallen under suspicion. The type of small-pox now prevalent is so mild that the recorded deaths are almost negligible. As regards diphtheria, the immunisation of the staff of isolation hospitals against this infection is widely practised, and an experiment on a large scale has been made with Edinburgh school-children, a scheme which is meeting with the approval of the great majority of the parents. It would, perhaps, be premature to call for such a campaign against rheumatic diseases in children, in view of the fact that their ætiology has not been fully worked out. But we know enough to prevent a great part of rheumatic heart disease, with its crippling effect on the community. We also have enough knowledge entirely to prevent damage to eyesight from ophthalmia neonatorum and to prevent congenital syphilis. There can be little doubt, too, that maternal mortality from childbirth could be readily halved if the methods practised, say, by the obstetric unit of St. Thomas's Hospital, could be put into general operation. There are districts in this country where 80 per cent. of the births are attended by midwives who call in medical aid in about 25 per cent. of their cases. If it were possible in one of these districts to hand over the whole of the obstetric work—ante-, intra-, and post-natal—for a few years to a small panel of skilled obstetricians it would be seen what such close coöperation could achieve. A scheme of this sort has already been put forward in Glasgow. Bovine tuberculosis in the human subject could be stamped out at once if all milk were rendered safe before ingestion. Health Weeks and Baby Weeks provide for the education of the public on general lines. It may be worth considering whether a local campaign against certain definite diseases in the area would not arouse more enthusiasm than does general propaganda.

AN ALLEGED CONSPIRACY OF SILENCE.

SOMETIME in October Mr. Percy Dunn wrote an article in the *Daily Mail* dealing with Dr. J. A. Shaw-Mackenzie's prolonged attention to cancer problems, and there is no doubt that Dr. Shaw-Mackenzie has been unremitting in his work, though there is no general belief that his results have the significance which appears in some quarters to be claimed for them. A passage in Mr. Dunn's account of Dr. Shaw-Mackenzie's enthusiastic concentration upon his self-imposed task (Mr. Dunn's description) has brought us certain communications as to our own attitude. That passage runs: "Dr. Shaw-Mackenzie has been largely debarred from giving professional publicity to his discovery; in a sense perhaps a policy of caution has probably accounted for this conspiracy of silence and neglect." If Mr. Dunn had consulted our columns, he would not have accused THE LANCET, we think, of conspiring to neglect Dr. Shaw-Mackenzie, whose communications to THE LANCET on the subject have been frequent, while in them, it seems, can be found the substance of the claims made for him by Mr. Dunn.

Accusations against newspapers of conspiring to the disadvantage of particular writers because they hold particular views can be easily brought, and such an accusation has been brought against this paper in connexion with a communication received from one of the staff of the Battersea Hospital last June. The paper was returned to the author when no space could be found for it—alas, a frequent occurrence here—but, on the suggestion being made to us that the rejection of the communication was held to be unfair, we invited the author to return it to us for further consideration, but no reply to the invitation can be traced. As far as this paper is concerned we do not admit Mr. Dunn's suggestion that a policy of caution regulates our acceptance of work that does not run on conventional lines; our attempt is to avoid the raising of false hopes by premature endorsement of claims made for such work. The *ipse dixit* of the author may be perfectly honest, and quite justified in his own view, without there being sufficient warrant for accepting the conclusions, when it becomes a duty to refer the communication back to the author. If the arguments in favour of those conclusions are not reinforced, either through further work done by the author, or by work undertaken in other laboratories by independent observers, it is not a conspiracy of silence to decline to publish repetitions of the original statement; this is not being unduly cautious—it is merely securing in our pages more space for reports that appear to be progressing valuably.

Lastly, a statement is not necessarily valuable because it is new. If an author is unable to furnish arguments other than novelty for the insertion of a paper, it is right to believe that it will be no disadvantage to the medical public if they have to wait until the researches have got to a further stage. If the scientific worker requires that assistance from his colleagues, generally or specially interested, which is afforded by discussion at an appropriate meeting of one of the medical societies, he should take the opportunity of securing it. At such a discussion many a man may find that his individual conclusions do not coincide either with the clinical experiences or the laboratory findings of those who may be equally qualified (and even better qualified) than himself to make pronouncements. A communication which has safely emerged from such a reasonable ordeal is never refused by a responsible medical journal, however new its theories or revolutionary its doctrines—it is, on the contrary, welcomed, with the idea that it may contain the records of an advance, or may, anyhow, become a useful focus of activity.

THE PATHOLOGY OF OXALURIA.

THREE theories have been put forward to explain the origin of oxalic acid in the organism: (1) the decomposition of uric acid either in the organism or in the urine; (2) the oxalic acid introduced with food is absorbed and then excreted; and (3) insufficient oxidation gives rise to delayed metabolism of all aliments, or of some of them, which results in the production of oxalic acid instead of a more oxidised body. Dr. E. Lombardi, of the University of Naples, has recently published [1] some interesting researches made with the object of testing the truth of these theories. In collaboration with Prof. Piccininni he showed last year that oxaluria could be induced experimentally in immune individuals by the administration of a special strain of the colon bacillus, which he isolated from the fæces of oxalurics and which was markedly oxaligenous in vitro. Very conflicting results have been reached by experimenters studying the elimination of oxalic acid either after the introduction of uric acid and urates into the organism or after various kinds of food. This finds an explanation in the fact that the true fount of the production of oxaluria escaped them. In fact, granted that the formation of oxalic acid and the consecutive oxaluria are in relation with special microbic fermentations of the intestinal content, it is possible to explain the uncertain and contradictory results of various authors according to the special conditions of the gastro-intestinal apparatus of the individuals they used in their experiments and also according to their microbic intestinal flora. With regard to the food theory, if the oxalic acid contained therein can in a small degree increase the ordinary elimination by the urine, no one any longer admits that it is the exclusive cause of oxaluria. At the most it can give rise to a transient oxaluria just as the introduction of a large amount of saccharine matter may produce a transient glycosuria without there being any true diabetes. The author's discovery of an oxaligenous strain of *B. coli* would seem to confirm the theory of Ogden

[1] La Riforma Medica, No. 37, Sept. 13th, 1926.

and Toepfer of the intestinal origin of oxaluria, and the further set of experiments just published were undertaken to show what is the action of this special microbe in inducing oxaluria in individuals who are free from it and to compare in the same individuals the oxaluria produced by the ingestion of food rich in oxalic acid with that induced by the special *B. coli*. In his first series of experiments on five patients suffering from tabes, pituitary tumour, post-encephalitis, diabetes, and Graves's diseases, who were free from oxaluria and to whom he administered cultures of *B. coli oxaligenus* with a diet free from oxalic acid, he succeeded in inducing a more or less marked oxaluria in which the amount of oxalic acid eliminated in 24 hours was estimated accurately. In the second experiment three of these same patients (with tabes, pituitary tumour, and post-encephalitis) were given 200 g. of spinach daily and it was found that the urinary elimination of oxalic acid showed only a very small increase, an amount very much below that produced by the oxaligenous germ. In a third experiment, on a patient who had passed an oxalate of lime calculus and on two diabetics of long standing, it was found the greatest oxalic elimination occurred with a mixed diet, in comparison with a purely carbohydrate or purely proteid diet. These facts, according to Dr. Lombardi, may be explained in the following manner: the intestinal fermentation which changes according to the variations in diet offers certain conditions more or less favourable to the activity of the oxaligenous germ, which in its turn causes the oxalic fermentation of the carbohydrates and hence a greater absorption and increased elimination of oxalic acid in the urine.

Some results of investigating the metabolic aspect of oxaluria have just been put on record by Prof. G. Viale,[2] who has studied the effects of injections of insulin, adrenalin, and phloridzin on the formation and excretion of oxalic acid, and also the results of removing the pancreas. He concludes that excess of oxalic acid in the organism is due to irregular metabolism of carbohydrates—an irregularity for which he blames the pancreas. He summarises the experimental results as follows: (1) The injection of insulin does not alter the amount of oxalic acid in the blood. (2) This injection lowers notably the elimination of oxalic acid by the kidneys; it has an equal effect in reducing the large amount passed by diabetics. (3) On the other hand, the injection of adrenalin much augments the excretion of oxalic acid, an effect which becomes daily greater for some days, in conjunction with an increased excretion of glucose. (4) The removal of the pancreas increases the excretion of oxalic acid. (5) Phloridzin produces no noteworthy change.

IDENTICAL TWINS.

IT has been suggested that the habit of women to produce only one child at a time is a relic of an arboreal ancestry. Since they came to earth they have, to a small degree, reverted to the original habit of nourishing more than a single ovum, and twin births, the individuals of which are no more like one another than their brothers and sisters born separately, are not uncommon. But they have also learned, apparently, to increase their productivity by making more than one individual out of a single ovum—an art highly developed in some armadillos, in which one ovum normally gives rise to as many as eight or ten young by a process of fission and budding. In lower animals it has been shown beyond doubt experimentally that one of the two cells into which an ovum divides at its first segmentation can give rise to a whole complete individual, and there are many reasons for supposing that the same thing happens in man. Anatomical or functional separation of the parts of an ovum in the early stages of its division probably accounts for a number of human abnormalities. At one end of the scale we have ovarian teratomata, in which the dermoid represents an individual which has made an almost complete failure of development. Better success in various degrees is shown in the different kinds of double monsters, some of which are normal enough to survive as Siamese twins. And at the top of the scale we reach the twins, both from a single placenta, which have a degree of resemblance to one another which has excited notice from the earliest times. The whole series of facts leaves little room to doubt that these so-called identical twins really come from a single egg: it is clear, however, that we cannot affirm that all uniovular twins are identical in their make-up, though it is difficult to understand how they can be otherwise. A good example of such twins has lately been studied by Dr. G. P. Crowden (*Guy's Hospital Reports*, October, 1926, p. 379), who gives exceptionally full details of two brothers who seem to be more like one another than a pair of peas. Their size, shape, appearance, rate of growth, finger-prints, differential blood counts, illnesses, scholastic records, mental characteristics, muscular power, and everything else which was measured, all show the extraordinary degree of similarity which has been repeatedly described. In this particular case the resemblance has, perhaps, been increased by the fact that both have spent their lives in exactly the same environment. Most identical twins are likely to do this, at first because they are twins, and later because they are so similar mentally and psychically. What is particularly needed is the study of examples where the two individuals have been separated and brought up in different ways. Cases of this are probably very rare, so that any opportunity of examining them in detail should be taken; it is a unique chance of getting some clear light on nature versus nurture.

[2] Revista Sud-Americana de Endocrinologia, November, 1926.

As we go to press we learn that the summons against Prof. E. B. Verney, for having unlawfully in his possession a dog, knowing it to have been stolen, was dismissed by the Clerkenwell magistrate, who awarded £5 5*s*. costs against the prosecution.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt.-Comdrs. to be Surg. Comdrs.: E. Heffernan and W. J. Morris.

The following appointments have been made:—Surg. Comdrs.: G. F. Syms to *Erebus*; H. E. R. Stephens to *Calcutta*, addl., and as squadron medical officer; W. H. A. Sinclair-Loutit to *Capetown*; R. F. Quinton to *Maidstone*; and J. G. Danson to *Emperor of India*.

ROYAL ARMY MEDICAL CORPS.

Majs. R. G. Martyn, A. Irvine-Fortescue, and R. B. Price are secd. for service under the Colonial Office.

Capts. to be Majs.: A. E. S. Pringle-Pattison, H. D. F. Brand, F. C. Atkinson Fleming, D. C. Monro, G. S. McConkey, J. A. L. Wilson, and H. Alcock.

ARMY RESERVE OF OFFICERS.

Col. A. H. Waring, late R.A.M.C., having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

TERRITORIAL ARMY.

Cols. A. W. Sheen, Sir H. E. Bruce Bruce-Porter, and E. J. R. Evatt, having attained the age limit, are retd. and retain their rank, with permission to wear the prescribed uniform.

Lts. G. T. Symons and K. S. Roden to be Capts.

W. Niven to be Lt.

ROYAL AIR FORCE.

Flight Lt. (Hon. Squadron Leader) W. R. Reith relinquishes his temporary commission on account of ill-health.

INDIAN MEDICAL SERVICE.

Lt.-Col. G. Browse to be Col.

ROYAL SURGICAL AID SOCIETY.—The income for the year reached the "record" figure of £49,000. Nearly 25,000 patients were supplied with 33,594 appliances.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCIII.—TREATMENT OF FRACTURES OF THE JAWS.

THE great majority of fractures of the jaws met with in civil life occur in the mandible. Fractures of the body are almost invariably compound, for the mucous membrane covering the bone is easily torn. Fractures of the lower part of the ascending ramus may also be compound, but those in the upper part, as well as fractures in the region of the condyle, are usually simple. In the mandible the site of fracture may be through the body, the ascending ramus, coronoid process, and condyle. A. G. Allen,[1] in a useful review of the subject, found that over 90 per cent. of all fractures of the mandible occurred in the body. Of these the commonest site is in the region of the canine tooth, the next frequent place is in the neighbourhood of the third molar. Although a fracture may occur as the result of disease—e.g., a tumour—by far the commonest cause is direct violence such as a blow or fall.

As with other bones a fracture of the mandible is followed by displacement of the fragments, which depends on the pull of the various muscles attached.

A fracture in the region of the insertion of the masseter may be splinted by that muscle so that little displacement occurs. For the same reason fractures of the ascending ramus may give little objective sign. Fractures of the condyle are rare, and may not cause any displacement, though sometimes there is a deviation of the chin toward the injured side owing to the action of the external pterygoids. The chief objective sign of displacement is an inability to close the teeth properly. An exact reduction of the fragments in their anatomical relationship is important, since a malunion, even if only slight, will upset the occlusion and impair mastication, and may necessitate extraction of the misplaced teeth later. In patients with few or no teeth imperfect reduction is of less moment for obvious reasons, though it should be aimed at as the ideal.

Preliminary Measures.

A radiograph should be regarded as an essential part of the diagnosis of a fractured jaw even though the fracture may be obvious. Apart from its value as a safeguard to the practitioner a radiograph may show that a tooth is involved in the fracture and will require extraction. It is not uncommon for an obvious fracture through the body to be associated with a fracture through the ascending ramus on the opposite side. If a radiograph cannot be obtained at once there is no need to delay treatment, for the construction of a splint will take some days during which time a radiograph can be obtained. As soon as possible the teeth should be cleaned up, tartar removed, and loose roots or obviously septic teeth extracted. Since the majority of fractures are compound the presence of dental sepsis will exercise an unfavourable effect on the result and will be likely to delay union.

In general, the extraction of the teeth immediately adjoining the fracture is a wise measure and they should be retained only when their presence appears to be essential to reduction and fixation.

Reduction and Fixation of the Fracture.

The efficient treatment of the vast majority of fractured jaws depends on the mechanical control of the fragments, which are usually considerably displaced. This necessitates a splint of some kind, the construction of which is only possible in a dental laboratory. It still sometimes happens that a patient under the care of a medical practitioner is not seen by the dental surgeon until several days have elapsed. Even if the general condition of the patient is so serious that the treatment of the fracture must be deferred, it would mostly be to his advantage that the dental surgeon should see him as soon as possible. The longer treatment is delayed the greater will be the displacement and the more difficult its reduction, owing to muscle spasm.

Fractures of the Body of the Mandible.

Fractures in the body of the mandible may be divided into three groups: (*a*) those in which there are teeth present on the posterior fragment; (*b*) those in which there are no teeth on the posterior fragment, or if present, the teeth are useless as anchorage for a splint; (*c*) fractures of the body in an edentulous jaw.

(*a*) *Where Teeth are Present on Posterior Fragment.*—In the first group the best type of splint is the metal cap. This splint covers the crowns of the teeth on each side of the fracture and is fixed by cement. It is easily kept clean and though conspicuous, does not interfere with normal function and allows the patient to follow his ordinary life. It provides secure fixation of the fragments and gives an excellent result.

An impression of both jaws is taken in modelling compound. Any displacement will, of course, be reproduced in the lower model. This is sawn through at the site of fracture, and the two halves articulated separately to the upper model and joined together. This corrected model is used to construct the splint which, when completed, can only be fitted to the teeth when the fragments have been reduced; conversely, when the splint is cemented into place, a satisfactory reduction has been effected. The splint may be made of silver and gilded. If there is spasm of the muscles which prevents reduction it may be necessary to fix the splint under a general anæsthetic. In this case great care must be taken not to use heat in drying the teeth prior to covering them with cement, for a fatal explosion has been recorded where ether was being used.

In some cases in which the displacement is great and difficult to reduce or the teeth do not afford very secure anchorage, it may be advisable to make a similar splint for the upper teeth. Studs are soldered to the outer surfaces of both splints and the jaws kept closed by means of wire ligatures fastened to the studs.

(*b*) *Fractures of the Body with Absence of Teeth on the Posterior Fragment.*—In these cases the main difficulty lies in effective control of the posterior fragment. A lower metal cap splint covering such teeth as are present should be constructed, and a vulcanite block should be made to fit the alveolar ridge of the posterior fragment (similar to a denture). This can be secured to the cap splint by a variety of mechanical devices. The surface should articulate with the crowns of the upper teeth corresponding to the lower fragment. An upper cap splint is also necessary and the jaws must be kept closed. It may not be possible to reduce any displacement of the posterior fragment which has already occurred, but further displacement will be prevented.

(*c*) *Fractures of an Edentulous or nearly Edentulous Mandible.*—If no teeth are present, the cap splint is useless, and the Gunning splint is the best. This is simply a block of vulcanite fitting both alveolar ridges, or if maxillary teeth are present, fitting over their crowns. The splint is removable and is held in place by a four-tailed bandage. An anatomically perfect reduction may not be achieved, but since the patient is edentulous there is no occlusion to be disarranged, and the worst that is likely to happen is that if the patient wears dentures, fresh ones will be needed later. Since the Gunning splint is only a modified pair of complete dentures, the patient's own dentures, if he has any, may be used as a temporary splint, and may be all that is needed to secure sufficient fixation until consolidation occurs.

Fractures through Ramus or Condyles.

Fractures through the ascending ramus or condyles are rare. A condylar fracture may cause considerable displacement. Double-cap splints should be made and cemented to the teeth, and the jaws kept closed. If the displacement is slight, a four-tailed bandage may be sufficient. A word may be said here as to

[1] Dental Record, 1925.

the use and abuse of the four-tailed bandage. A four-tailed bandage is quite useless where there is displacement of the fragments, since it does not control them, and if union occurs the displacement is perpetuated with disastrous results. As a temporary expedient while splints are being constructed, or as an ancillary measure to provide rest for the jaw after the splint has been adjusted, it is useful. In the comparatively few cases in which displacement is absent the four-tailed bandage may suffice.

Fixation by Interdental Wiring.

A method of treatment applicable to fractures with teeth standing is the application of interdental ligatures of wire fastened to the teeth of both jaws, which are approximated and fixed together. An excellent account of this method will be found in Blair and Ivy's "Essentials of Oral Surgery" (p. 166 et seq.). Briefly, the method is as follows:—

Brass wire such as is used in orthodontic practice is best. A loop of wire is passed between the necks of two teeth from within outwards so that the loop lies externally. The free ends are passed round the necks of the two adjoining teeth through the interdental spaces. The loop is secured by a towel clip and the ends drawn tightly and twisted together *above* the loop in the lower jaw and *below* the loop in the upper jaw. This is done with each pair of teeth in both jaws. The process is tedious, and as it is impossible to avoid pricking the gum, a general anæsthetic may be needed. The mandible is approximated to the maxilla by passing a strand of wire through each pair of corresponding loops and twisting the ends together. The reduction of the smaller and most displaced fragment should be effected last. If complete reduction is impossible owing to muscle spasm, it will be found that in a few days the approximating ligatures can be tightened and complete reduction easily obtained.

The guide to complete reduction is the restoration of normal occlusion. Since there is nothing intervening between the crowns of the teeth, it is possible to get a very good result. The disadvantage of the method is that the jaws must be kept closed for several weeks and the patient fed on liquid diet. On the other hand, the method obviates the need of a complicated apparatus. It is easy to judge of the progress of callus formation without removing the ligatures, whereas with a cap splint, except by taking a radiograph, it is impossible to be certain when consolidation is complete. The method has its uses, but where possible a cap splint should be used, for it interferes less with the patient's comfort.

After-care.

An abscess under the jaw may follow a fracture, and must be treated by incision. Careful attention to the hygiene of the mouth both before fixing the splint and subsequently will often prevent its formation. Some necrosis is almost inevitable. Treatment should be expectant and limited to regular syringing daily. As a rule the sequestra come away without surgical intervention. Careful and regular syringing of the sinus at the site of fracture as well as of the rest of the mouth is essential. An excellent mouth-wash consists of phenol 1 in 80, to which a few drops of tincture of iodine are added. It is, however, the mechanical flushing with fluid rather than the antiseptic which is important. In an uncomplicated case union usually occurs in about six weeks. If there is much suppuration or necrosis which suggests that union may be delayed, it is advisable to take a radiograph before removing a cap splint, since in taking it off it is often spoiled and cannot be reapplied. The patient should be warned that for some months care should be taken not to put any strain on the jaw.

Fractures of the maxilla are treated on similar lines to those of the mandible, except that a single splint applied to the upper teeth is all that is necessary. Fractures of the body of the maxilla do well, but fractures involving the avleolar process often lead to a considerable loss of bone, together with the attached teeth.

FŒTAL MORTALITY.
A CLINICAL AND PATHOLOGICAL STUDY.

THE latest addition to the Special Report Series of the Medical Research Council [1] embodies a clinical and pathological study of 1673 dead births and neonatal deaths. It follows on and confirms Mr. Eardley Holland's report "On the Causation of Fœtal Death," published in 1922.[2] The schedule sent out to the coöperating workers asked for details of the health and economic position of both parents, but it was recognised that inquiry into the paternal history was a counsel of perfection, and this part of the problem was not handled seriously. Unfortunately, even the clinical histories of the mothers and their confinements were not all that could be desired, and the authors point out that general deductions must be made with the utmost caution, and plead for a more careful record of hospital cases. A post-mortem examination was made on every child and on every placenta that could be obtained. The high proportion of deformities in the series may, the authors think, be due to the fact that bodies of deformed children are more readily submitted for examination than are normal ones.

The Causes of Death.

A clinical classification was decided on for all cases. The figures from the various centres where the work was carried out—London, Glasgow, Liverpool, Edinburgh, and Cardiff—are tabulated and compared with those previously published by Whitridge Williams in Baltimore, Holt and Babbitt in New York, and McQuarrie in San Francisco. Considering the independence of all these researches the similarity of results is remarkable. In all of them "complications of labour" heads the list, ranging from 22·4 to 37·1 per cent. In the London figures "antepartum hæmorrhage" follows close behind with 22·3 per cent., but the other series rate it much lower in the scale and give a high place to maternal diseases and placental states. Syphilis is the generally accepted third; Holt ascribes only 8·3 per cent. of cases to it, but McQuarrie and Eardley Holland both put the percentage at 15. Running it close come "toxæmias of pregnancy" and after that "fœtal states." The figures are further tabulated and compared according to whether the child died before, during, or after labour. Syphilis, toxæmias of pregnancy, and antepartum hæmorrhage were found to account for a very large proportion of the macerated fœtuses, although the 80 per cent. stated by Whitridge Williams to be due to syphilis proved to be too high for this series. Infections played a large part in the neonatal deaths, killing no fewer than 88 out of 97 cases, if parenchymatous nephritis were regarded as inflammatory. In over half the cases there was some associated maternal condition or complication.

The Mother.

In the absence of histories of mothers bearing live children no absolute deductions could be drawn from the story of maternal illness, but a group of 33 deaths primarily due to maternal states could be separated out. Of these 11 were macerated fœtuses associated with cardiac, renal, and pulmonary conditions, hyperemesis and intussusception. Among the cardiac and renal cases where labour was induced there was a high incidence of tentorial tears and cerebral hæmorrhage. The percentage of dead births in cases of certain maternal syphilis was 28·6, in possible syphilis 59·1. There were many women who had had no dead birth or abortion before the pregnancy under investiga-

[1] Special Report Series No. 109. Eardley L. Holland, M.D., F.R.C.S., and Janet E. Lane-Claypon, D.Sc., M.D. London: H.M. Stationery Office. 1926. 3*s.* 6*d.*

[2] Reports on Public Health and Medical Subjects, No. 7. Published by the Ministry of Health.

tion. Syphilis was sought in 95 cases of toxæmia of pregnancy, but found only in one. It is surprising that one-third of the records give no urine analysis in toxæmia; in the remaining two-thirds albumin was present in all but one of the eclamptics and in all but two of the cases of albuminuria of pregnancy. The placentæ in 31 out of 35 cases showed infarcts with or without clot or hæmorrhages.

The Placenta.

Only 11 deaths are ascribed to placental states, nine of them being macerated fœtuses. The only conditions recognised were infarction and excessively small placenta. Bleeding from the placental site during pregnancy caused 251 deaths, 122 being cases of placenta prævia. No case of placenta prævia occurred among the deaths primarily due to syphilis and there were no signs of syphilis among the 122. There had been signs of hæmorrhage several days or weeks before labour in most of the cases, and apparently little notice had been taken of the symptom. Among the cases of accidental hæmorrhage there was one positive Wassermann only, and in them also the bleeding nearly always appeared first before labour.

The Labour.

The proportion of intracranial tears was high in the 900 non-macerated and non-deformed children, amounting to one-fourth of the cases. Very complex tables are given correlating the tears with the presentation, the method of delivery, and the primary cause of death. By far the greater number occurred in breeches and persistent occipito-posteriors, and in cases associated with complications of labour and syphilis. About one-half of the cases in which forceps were applied had tentorial tears, even if the forceps had only been applied once. Intracranial lesions were found in about one-third of all cases of version.

Contracted pelvis accounted for 175 deaths, and the records show that proper antenatal care would undoubtedly have saved many of these. There were 142 abnormal presentations and 58 difficult or prolonged labours, half of the latter being in primiparæ. Prolapse, coiling, or knotting of the cord appeared to be the primary cause of 41 deaths; these presentations were nearly all vertex.

Fœtal Deformity and Prematurity.

One hundred and thirty-eight cases fell into this section, 25 of them being macerated and 21 alive at birth; 40 per cent. were full term and there was the usual high proportion of breech presentations. In 47 instances there was no apparent cause of death other than prematurity; in 22 of these there was asphyxial cerebral hæmorrhage, and in 10 there were other hæmorrhages as well.

Unknown Causes.

When the classification was complete there remained over 40 macerated fœtuses, 36 fresh dead babies, and 30 neonatal deaths. The age at birth, at death, the weight and the length varied and offered no points for attention. The urine of the macerated fœtuses contained sugar in two cases and a trace of albumin in three.

Eighteen of the placentæ were normal, while 21 showed infarction or fibrosis. Where the previous obstetric history was recorded 37 were primiparæ, 35 had had no previous dead birth, while 16 gave a history of stillbirth. Of these 106 cases no trace of any cause could be assigned in 56, but in 35 there was more or less asphyxia.

Conclusions.

The authors feel that there is no doubt that maternal morbidity is closely related to fœtal and to maternal mortality, and their results show that not less than 25 per cent. and probably more of all dead births are due to manipulations. Therefore the only line of prevention is that of adequate antenatal supervision.

RESEARCH IN MENTAL DISEASE.

THE output of research on mental disease is steadily increasing year by year. Naturally a large proportion of the work comes from the special research institutes, whose equipment and endowments make the way smooth, but it is encouraging to note how many of the mental hospitals contrive, although handicapped by inadequate laboratory facilities and a great quantity of routine work, to publish research notes of real significance.

Basal Metabolism.

The Joint Board of Research of the City and University of Birmingham, in its report for the year ending March, 1926, records much detailed work on basal metabolism, and the figures of 29 experiments on patients and 53 on controls are published, preliminary to discussion. The work has shown the great importance of conscious and unconscious muscle-relaxation, which has not, perhaps, been taken sufficiently into account in previous statistics of the bag-methods. A normal person sitting completely relaxed may show a metabolic rate lower than that usually regarded as evidence of hypothyroidism.

Malarial Treatment of General Paralysis of the Insane.

It is now nearly ten years since Wagner-Jauregg, experimenting with all kinds of non-specific protein irritants, decided that the reaction to benign tertian malaria was more efficient than that shown to any other substance in relieving the symptoms of general paralysis of the insane. He published the results of the treatment in over a thousand cases, and since then a large number of patients in British mental hospitals have been treated. The annual report of the Board of Control provides an opportunity for reviewing their results. In Birmingham 12 cases have been treated, 8 with mosquitoes and 4 with malarial blood; the incubation period varied from 3 to 25 days. Two patients died from lung conditions, and seven were definitely worse mentally during the febrile period. Four bedridden patients were sufficiently improved to get up and help in the wards, and two less advanced patients have recovered sufficiently for discharge. One case was worse mentally after the treatment, but showed physical improvement, while mental improvement was always accompanied by amelioration of the physical condition. Fine movements became better coördinated, but the reflexes did not improve. The colloidal gold test and blood Wassermann remained unaltered, but the cerebro-spinal Wassermann was always considerably reduced and in one case became negative. At Wadsley (Sheffield) examination of the cerebro-spinal fluid showed that the specific reactions were reduced in a large percentage. At Whittingham it was found that the Braun-Husler and acetic-anhydride reactions were generally positive before malarial treatment and negative after it. The Birmingham investigators note that all 12 cases had advanced disease of the teeth and jaws, 3 had buried tonsillar abscesses, and 7 gave evidence of old disease of the maxillary antrum. They attach considerable therapeutic significance to the removal of these foci of sepsis, and discuss the effect of their presence on the malarial treatment.

At the Cardiff Mental Hospital 14 cases have been treated by subcutaneous injection of whole or defibrinated malarial blood; 3 showed physical but no mental improvement, and 4 recovered sufficiently to be discharged to work in a subordinate capacity. The longest remission so far on record has lasted for two years. Whittingham has transmitted a benign tertian strain through 60 generations by direct subcutaneous inoculation, and can supply it to hospitals requiring it. The strain has been carefully studied morphologically, and appears quite unchanged, and to have undergone no increase in pathogenicity

or virulence. Five rigors have been found quite enough; 117 cases have been treated, and of these 27 have been discharged apparently well, some of them over two years ago; 17 are earning their living. There were 20 deaths out of the 117 treated. The medical officer deprecates the use of mosquitoes for infection, as the percentage of malarial relapses is 55 per cent. with the insects and less than 2 per cent. in his series. Patients who have relapses in their own homes may spread the disease.

At Winwick (Lancashire County Mental Hospital) 7 cases were discharged out of 63 treated, and 7 more were considerably improved. Both here and at Claybury the existence of an acquired immunity has been established. Inoculations of relatively immune patients by mosquitoes instead of blood slightly lowered their resistance, and a new strain invalidated it. It had no relation to the number of rigors in the primary attack or to the blood grouping of donor and recipient.

At the Claybury Mental Hospital also workers have perfected a freezing method whereby defibrinated malarial blood can be sent by post to districts requiring it (THE LANCET, 1925, i., 793), and have investigated the blood of patients under malarial treatment. There is a preliminary erythrocytosis in all cases, followed by an anæmia which within three weeks gave way to another erythrocytosis. The hæmoglobin varied with the blood cells, and the number of parasites varied with the temperature. Sometimes there was a great destruction of parasites during the fever.

At Severalls (the Essex County Mental Hospital) malarial blood injection is routine for all early cases: 18 have been treated, of whom 1 died, 3 were greatly benefited, and 6 were discharged; 4 of the latter earn their living. At the Sunderland Mental Hospital 14 unselected cases were inoculated subcutaneously with malarial blood from Whittingham, and were allowed to have ten rigors. There was one death from pneumonia, one case of jaundice, and two instances of great improvement. At the Leicester City Mental Hospital trial has been made of malaria for neurosyphilis, but no benefit resulted.

Intestinal Infections.

Twenty-three per cent. of the supposedly healthy transfer-admissions at Wakefield Mental Hospital were found to give a positive Flexner agglutination, pointing to the risk of mixing transfers from other mental hospitals with healthy patients. Anti-dysenteric vaccination was used with great success. A number of other hospitals have investigated the whole question of typhoid and dysentery as the result of outbreaks in their wards. At Parkside the cases of intestinal disorder were found to fall into two groups, due respectively to infection by Flexner bacillus and by *Streptococcus fæcalis*. Arising out of a typhoid investigation at Birmingham, a number of agglutination tests have been carried out, and these figures also are published in the annual report of the Joint Board of Research. They show that many patients must have been infected at some time in their lives. Many fæcal specimens showed organisms of the paratyphoid group which did not agglutinate with the virulent types, and it seems probable that much chronic ill-health may be caused by these varieties. The bacillus of Friedländer was found in 54 per cent. of the patients at Rubery Hill, at one time or another, with a distinct seasonal rise in September and October.

At the laboratory of the Scottish Western Asylums Research Scheme much work has been done on these infections. An intestinal epidemic at Smithston Asylum was traced to a urinary carrier after about 400 specimens of excreta had been examined without result. At Dykebar a persistent carrier was found with no history of any illness related to typhoid. The report of this hospital endorses the recommendation of the Scottish Board of Health that every new patient in an institution where typhoid has occurred should have the blood examined for the Widal reaction on admission.

Septic Foci.

The Birmingham investigators found diphtheroid organisms and streptococci within the cervical canal in a large proportion of 250 female cases examined on account of gynæcological disturbance. Brain material was mostly sterile, but streptococci were found in a few specimens. An attempt is being made to correlate the bacteriological, biochemical, and histological investigation of post-mortem material. The Scottish Western Asylums laboratory found bacterial infections of the urinary tract in a good many patients, and distinct mental improvement followed their effective treatment. The laboratory of the Scottish Asylums Pathological Scheme has published work on the paths of infection to the brain, meninges, and venous blood sinuses from neighbouring peripheral foci of inflammation (*Journal of Laryngology and Otology*, xli., 1926).

Drugs.

At Birmingham experiments on animals with hypnotic drugs have been continued, and striking histological changes in the white matter of the central nervous system have been demonstrated. Mucoid bodies, resembling but not identical with amyloid, can be produced at will by oral or subcutaneous administration of these drugs, and are associated with changes which suggest alteration in the metabolism of the neurones. The permeability of the brain membranes in general paralysis of the insane and in animals has been investigated, and there seems hope that the prognosis may be guided by the permeability ratio. Papers dealing with the estimation of iodine in thyroid were published during the year. Septic infection and tuberculosis were shown to be accompanied by great variation in the iodine content.

Workers at the West Park London County Mental Hospital are convinced that hyoscine has a specific beneficial action in encephalitis lethargica, and that its prolonged use does no harm. They make the interesting suggestion that the hysterical symptoms in this disease, and perhaps in other conditions, too, are due to lesions of the basal ganglia.

Investigations on the Blood in Mental Disease.

A biochemical study at Whittingham showed no evidence of poisoning by bilirubin pigments, and established that the fat content was normal. All new admissions at Cardiff are tested by the van den Bergh test for bilirubin. Non-protein nitrogen was found higher than normal in 12 out of 16 Whittingham cases of melancholia. Research at the East Sussex County Mental Hospital revealed a hypocholesterinæmia in a number of dementia præcox patients. The blood calcium in 50 new admissions was found remarkably constant. The Cardiff City Hospital found that phosphorus in plasma and cerebro-spinal fluid did not differ in quantity amongst psychotic patients from that normally found in controls. Calorimetric investigations at the Maudsley Hospital and at West Park showed that a constant diminution in the peripheral flow followed emotional or intellectual stress and painful stimuli, amyl nitrite usually produced an increase and adrenalin a prolonged diminution. 1338 blood-pressure readings taken at Parkside (the Cheshire County Mental Hospital) showed that the systolic pressure is higher in melancholia than in the depressed phase of manic-depressive insanity, and raised in catatonia, and in all cases in response to agitation and excitement. If these emotions were prolonged, however, the pressure fell. In all groups the diastolic pressure varied within much narrower limits than the systolic. Radiant heat baths caused a marked fall, with a lesser fall in the systolic.

Carbohydrate Metabolism.

At Cardiff a large number of experiments were carried out on rabbits to obtain an average sugar-curve after the intravenous injection of adrenalin and to study the modifications of the curve produced by the previous injection of other substances. It

was found that thyroxin raised the adrenalin-sugar curve, while calcium chloride diminished it. Thyroxin and calcium together reduced the adrenalin and thyroid curve, but raised the adrenalin and calcium curve. At Whittingham it was found that the sugar content of the blood was normal in most cases, but that it was high in melancholia and low in epilepsy. The majority of post-encephalitic cases at West Park showed a hyperglycæmia after glucose injection; depression and stupor were associated with most profound abnormalities of carbohydrate metabolism, but the clinical pictures could not be correlated with the types of blood-sugar curve. It is possible that these curves may have a prognostic significance, and they can be brought nearly to normal by hyoscine. Staffordshire also found great variations in the carbohydrate metabolism, especially in cases with confusion or depression. Low sugar-tolerance was most often found in recent melancholia.

Epilepsy.

At Burntwood, the Staffordshire County Mental Hospital, it was found that extra carbohydrate in the diet made no difference, so that acidosis does not appear to be an important factor in this disease. Luminal was used on carefully-watched cases at the Devon County Mental Hospital, where they found it valuable but not in any sense a "cure." Hypodermic injections of luminal sodium were found at Rainhill to give very promising results in status epilepticus. At Sunderland allonal was tried, but without success.

Ultra-violet Light.

At Parkside the value of ultra-violet rays was investigated on 50 patients; there was marked increase in the weight, appetite, muscular activity, and cheerfulness. Manic-depressive cases and mild melancholias responded best. Deluded patients were less harassed and became more amiable. Dementia præcox was little affected, and melancholias with agitation and hypothyroidism were aggravated. There was no constant change in the metabolic rate, but the systolic blood pressure was slightly decreased. The results of radiant heat baths were examined in 72 subjects from among patients and staff, and it was found that sweating was considerably delayed in dementia præcox and slightly accelerated in maniacal patients.

Pellagra.

The Lancashire County Mental Hospital at Rainhill reports the case-histories and autopsies of two cases of pellagra, which brought the total number of known cases in this hospital to 56. One case was first diagnosed as myxœdema, and thyroid atrophy was found post mortem. Pellagra is also the subject of a study by the Herts County Mental Hospital, St. Albans, where seven cases were recognised during the last 14 years. In this series food deficiency seems to have played an important part, and it is suggested that the achlorhydria may permit proliferation of gastro-intestinal organisms with selective toxic action on the posterior and lateral tracts of the cord.

Miscellaneous.

Workers at the London County Mental Hospital, Long Grove, found measurable quantities of cholesterol in the cerebro-spinal fluid in 30 cases of general paralysis, but not in any cases of dementia simplex, dementia præcox, or epilepsy with insanity.

From West Park were published the results of research on laboratory aids to diagnosis. They consider that the serum Wassermann reaction should be a routine measure in all cases, and that where syphilis of the central nervous system is suspected the cerebro-spinal fluid should also be examined. Early diagnosis and treatment of the supporting and nutritional tissues of the central nervous system may prevent it from passing on to incurable disease of the parenchyma. They point out that no single reaction is pathognomonic of any particular disease, and that several tests must be performed and the clinical findings and therapeutic results taken fully into account. The acetic anhydride-sulphuric acid test was found almost as reliable as the Wassermann reaction in the diagnosis of general paralysis.

Renal function tests are being extended at the Devon County Mental Hospital in order to estimate the significance of albuminuria. In the diagnosis of neurosyphilis it appeared that the globulin reactions were reliable, as well as being easy to perform. Unna's polychrome methylene-blue was found better than the ordinary stain for cytological examination.

MEDICINE AND THE LAW.

The Check on Judicial Reports.

THE Judicial Proceedings (Regulation of Reports) Act, which became law on Dec. 15th, is of no small concern to the readers and writers of medical books and articles. It is true that there is a saving clause for "any publication of a technical character bona fide intended for circulation among members of the legal or medical professions," and that the recognised law reports will be published as before; but the medico-legal student who has been accustomed to find much relevant material in the daily newspaper may have in future to look elsewhere. The Act forbids the printing or publication "in relation to any judicial proceedings" of "any indecent matter or indecent medical, surgical or physiological details being matter or details the publication of which would be calculated to injure public morals." Limits are also imposed upon the reporting of divorce court proceedings. Breaches of the new Act are punishable on summary conviction, but no one is to be prosecuted without the Attorney-General's consent, nor can anyone be convicted except a proprietor, editor, master printer or publisher.

Time alone will show whether the results of the Act will be as excellent as its purpose, and whether the haste with which it was passed into law will be justified. Already the President of the Divorce Court has felt himself obliged to deliver a much fuller judgment than he would otherwise have done, so as to ensure publicity for the particular point he was deciding. Indeed, the administration of justice may be incompatible with secrecy. Well-intentioned legislators inserted in the Punishment of Incest Act of 1908 a section enacting that "all proceedings under this Act are to be held *in camera*." Time passed, and judges found that this want of publicity was keeping the country in ignorance of the criminality of an odious offence. In 1922, after a series of judicial recommendations, the section was repealed. The non-admission of the public to a court of law may, of course, often be justified. For reasons of State a trial under the Official Secrets Act, and for other excellent reasons an application under the Adoption of Children Act or the Guardianship of Infants Act, may be heard in private, while the Children Act of 1908 empowers the clearing of the court when a child is giving evidence of a certain nature. The regulation of reports, a course which many advocated after the publication of the proceedings in Russell *v.* Russell, is a further step. Some think a less drastic course might first have been tried—for example, judges might have been authorised by Parliament to declare in any particular case that no report should be published until the conclusion of the trial. This proposal might have checked sensationalism, and certainly, where baseless allegations had been made, it would have given the answer simultaneously. The Judicial Proceedings (Regulation of Reports) Act, however, is now the law of the land and must be obeyed. We may expect many metaphysical discussions when magistrates are asked to say whether medical, surgical, and physiological details are indecent and injurious to public morals.

Commencement of Acts of Parliament.

In view of the recent error of the Home Office—or, at any rate, of the learned counsel who prosecuted in the Kynaston case—in invoking the aid of an Act

of Parliament which was not yet in force, the medical profession may care to note those statutes of the recent session which have a postponed date of operation. A group of three come into force on New Year's Day; they are the Lead Paint (Prevention of Poisoning) Act, the Adoption of Children Act (for which the Lord Chancellor has just made three sets of rules of procedure for applications in the High Court, county court, and magistrates' courts respectively), and the Midwives and Maternity Homes Act—or, rather, that part of the last-named Act which deals wth the registration of maternity homes, the clauses amending the law as to midwives having taken effect last August. The new Coroners (Amendment) Act does not come into force till May 1st. Three other Acts are delayed until July 1st, 1927. These are the Public Health (Smoke Abatement) Act, the Births and Deaths Registration Act, and the Legitimacy Act. All the above-mentioned statutes have a fixed date; they do not require the elastic, but uncertain, method of fixing an "appointed day" by Order in Council or otherwise. Examples of this vaguer method are rare in the legislation of 1926, but one of them is the Fertilisers and Feeding Stuffs Act, which is to come into force on such date, not earlier than July 1st, 1927, as may be determined by the joint decision of the Minister of Agriculture and the Board of Agriculture for Scotland. This Act, rather more elaborate than the previous Act of 1906, which it is to supersede, is designed to check adulteration of poultry and cattle food and of soil fertilisers; it contains formidable lists of chemical substances, and is likely to provide analysts with additional employment.

The Lead Paint (Protection against Poisoning) Act.

The Lead Paint (Protection against Poisoning) Act, 1926, will come into force on the first day of the New Year. On and after that date every medical practitioner attending on, or called in to visit, a patient whom he believes to be suffering from lead poisoning contracted in or in connexion with the work of painting buildings, is required to send to the Chief Inspector of Factories, at the Home Office, London, S.W. 1, a notice stating the name and full postal address of the patient. In respect of every such notice he is entitled to a fee of 2*s.* 6*d.*, and for failing to send such notice he is liable to a fine not exceeding 40*s.*

THE MEDICAL INSURANCE AGENCY.

THE Committee of Management of the Medical Insurance Agency met at the House of the British Medical Association on Dec. 8th, Sir Humphry Rolleston in the chair, when an interim report was received, covering the activities of the nine months ending Sept. 30th and showing progress in various directions. Notably the Agency, through recommended policies, had completed 162 proposals representing £148,176, the largest figures yet recorded. The premium income on motor-car insurance had increased by over £1000, progress had been maintained in household, fire, and burglary insurance, and in accident and sickness insurance, while disputes in regard to settlements have been few.

A discussion took place as to the manner in which the Agency could best be of assistance to the Council of Epsom College when it was resolved to subscribe to the Foundation a sum of 200 guineas, being the amount required to obtain the maximum number of votes under the existing by-laws of Epsom College. It was further resolved that if the by-laws should be suitably altered or modified the Agency would consider a substantial increase of subscription, and that "pending the consideration by the Council of Epsom College of the advisability of altering or modifying the by-laws to meet the difficulty of allocating proportionate votes to subscribers of large and regular sums, the Committee of Management place a sum of £100 at the disposal of the headmaster of Epsom College for the purpose of assisting to defray the cost of education of deserving boys who are the sons of deceased or disabled medical men or women."

The following grants were made to medical charities in respect of the year 1926:—

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Poor Relief to Miners' Dependents.

ON Dec. 15th Lord Constable pronounced judgment in the Court of Session, in the note of suspension and interdict at the instance of certain owners and occupiers of land in the parish of Dalziel (Lanarkshire), against the parish council of Dalziel. Since May, 1926, the respondents had been making payments for the relief of the wives and children of miners who were out of employment in consequence of the dispute in the coal trade, and the purpose of the action was to test the legality of these payments. After a long and carefully argued hearing, Lord Constable found that the payments were "unwarranted and contrary to law, but saving always and without prejudice to the statutory power of the Board of Health to abstain from disallowing or surcharging such payments."

This decision affects the whole administration of Poor-law relief in Scotland, for the case was brought in order to ascertain the law. The decision, in effect, brings the position within the ordinary administrative procedure of the Board of Health in cases where payments made are found at audit to be illegal; the Board can surcharge the members of parish councils or not as it considers just. While, therefore, the payments, which were made in accordance with the circulars of the Board, were found to be illegal, this does not necessarily mean that the parish councils will be surcharged. Even if this were likely to happen, the whole position is changed by the announcement made on Dec. 18th from the Scottish Office: "The Government has considered the position created in Scotland by the judgment of Lord Constable. The Government has decided that it will be necessary, immediately Parliament reassembles, to introduce a Bill to legalise the payments made by parish councils for this purpose during the recent dispute."

So far as the past is concerned, therefore, the large expenditure incurred by the parish councils will pass on to the plane of ordinary expenditure; but the problem of what will be done in future stoppages remains. A man on strike is not unable to find work in the sense of the 1921 Scottish Act, and is, therefore, not entitled to relief under that Act. If he is able-bodied he is not entitled to relief under the ordinary Poor-law Act of 1845. The decision definitely shuts out also his dependents from relief under either Act. But the payments have been made to the tune of several hundred thousands of pounds. This decision is far reaching. It certainly clears the position for both the Board of Health and the Parish Councils.

Medical Symptoms and Surgical Operations.

On Nov. 30th Mr. A. Ernest Maylard read a paper before the James Mackenzie Institute, St. Andrews, on the Bearing of such Conditions as High Blood Pressure, Glycosuria, and Albuminuria on the performance of Surgical Operations. In high blood pressure, he said, it was not so much the symptom itself that demanded consideration as the condition on which it depended; for where the rise in pressure was due to

disease of kidney, heart, or arteries, grave lesions connected with these structures introduced factors of greater moment than the symptom they produced. Apart from exceptional cases, where the systolic pressure exceeded 240 mm. of mercury and the diastolic exceeded 140, the risks connected with operation appeared to be negligible. Dr. Charles Moots, of Toledo, U.S.A., suggested for practical purposes that in each case the pressure ratio should be considered. This was found by dividing the pulse-pressure by the diastolic pressure; it was considered "ideal" when it stood at 50 per cent., but when below 25 per cent. or above 75 per cent. it was "very grave." Mr. Maylard thought that there was no very serious risk or impediment to the performance of operations on patients suffering from glycosuria, as represented by diabetes, as was best illustrated by the success that had attended amputations for diabetic gangrene. Inasmuch as the disease could be very definitely controlled, and the patient benefited by the pre-operative administration of insulin, operations of expediency could be undertaken without any fear of untoward results; experience further proved that wounds healed as well as when the patient had no such disease. In considering albuminuria as it affected operation, more attention must be directed to the cause of the symptom than to the mere presence of albumin in the urine. Reason would suggest that when it was dependent on a pathological condition of the kidney, the gravity of an operation would be greatly increased; but experience indicated that unless the disease of both kidneys was very advanced, but little risk was added to the performance of an operation. Albumin in the urine dependent on most other conditions, and particularly when only a trace was present, was practically of no moment, even where an operation was no more than expedient.

(FROM AN OCCASIONAL CORRESPONDENT.)

Cancer and Heredity.

AT the recent Montreal Congress of Surgeons Dr. William J. Mayo suggested that the degree of malignancy might be attributable to the diminished activity of immunising processes rather than to the nature of the activating agent. Dr. Maud Slye, as the result of experiments on mice, concludes that the resistance and susceptibility to cancer are transmitted as simple Mendelian units, as is also the site of occurrence of the lesion, but that these may be modified by selective breeding. Similar conclusions were reached as regards cancerous metastasis. As an outcome of her experiments susceptibility is the recessive, resistance the dominant character. In mice the first cross between dominant and recessive types did not produce cancerous offspring. Chronic leukæmia in mice followed the same rules of heredity as cancer followed. Speaking a few days ago at the convention of the Logical Society held in Milwaukee, Dr. Slye gave it as her opinion that mating based upon a knowledge of heredity and eugenics would eliminate cancer from the human spcies in two generations. If the knowledge were available, any individual who knew himself to be by heredity susceptible to cancer could, by mating with a non-susceptible individual, prevent the occurrence of cancer in their children.

The American Red Cross Society.

The annual report of this society directs attention to the increasing toll of life taken on the highways through motor-car accidents, which has brought home the need for instruction in first-aid to all who drive or ride in motor-cars. Owing to the modern vogue of outdoor amusement and the desire for fresh air, new problems had arisen owing to large numbers of people playing or living at a distance from medical men and hospitals. No difficulty had been experienced in promoting first-aid instruction, the problem rather being to find ways and means of fulfilling the requests received for service. In many high schools, first-aid service was now included in the curriculum; to assist in the training of teachers special courses were conducted at the summer schools of the Universities of Maryland and Virginia. At the University of Kentucky, Temple University, Peabody Teachers' College, and some other institutions classes in first-aid went on throughout the year. In industrial life and on the railroads first-aid instruction is becoming universal. Another developing Red Cross activity is the "nutrition service."

Study of Criminals.

In a report just issued by Mr. Frank E. Wade, a member of the New York State Commission on Prisons, the New York County Penitentiary is condemned from almost all points of view. One reason for severe criticism is that in 1917 the penitentiary was designated as a clearing-house to provide psychiatric and medical clinics, combined with good hospital and detention accommodation, but these plans were never carried out. Almost one half of the multitude of minor offenders passing through this institution have some physical disability, apart from the mental disabilities which press for better diagnosis and understanding. In discussing the drug addicts, in all numbering 1111—of whom 701 were sentenced for being in possession of drugs, 193 were self-committed and 217 sentenced for crime—the report states that the present management of these cases is less humane than formerly. When transferred to Riker's Island, as used to be the case, they were segregated, were in the open air, and had some treatment and care of a special character adapted to their condition. At present they are treated as common criminals. Commissioner Wade regards such treatment as unjust when dealing with addicts who are self-committed or have no criminal record other than being in possession of drugs. Non-criminal addicts, he holds, should be committed to a public hospital, not kept in prison.

PARIS.

Medical Education.

A RECENT decree is proving rather severe on French medical students. Until recently students failing in one subject of the final examination were allowed to take this subject alone after the lapse of a few months, being credited with having passed the rest of the examination. The new rule is that candidates will only be allowed to do this if they have reached 70 per cent. of the possible marks in the subjects in which they passed; otherwise they must take the whole examination all over again. Illness sometimes leads to failure in a single subject, and many unfortunate students may have to spend an extra year at work owing to this rule, which will be serious if they have little money. The Minister of Public Instruction is carefully considering the students' side of the question. It must be admitted that insistence on high standards is very desirable, but the ruling should be elastic enough to permit just consideration of hard cases.

A report by Prof. Weiss to the Académie de Médecine suggests that students should spend more time on the preliminary scientific subjects—physics, chemistry, and biology—and recommends that medical schools should provide a special pre-medical education. Everything superfluous, he says, should be rigidly excluded from the curriculum, and laboratory instruction should be used extensively.

Treatment of Sleeping Sickness.

The drug known as "270 Fourneau" has proved valuable in the treatment of sleeping sickness, in tests made at the Pasteur Institute at Brazzaville, in the French Congo. Its effects are specially manifest in the second stage of the disease. The

initial dose should not exceed 0·3 g. per kg. body-weight, but may be gradually raised to 0·7 g. The amount given must be considerably reduced during the late second, and in the terminal, stage of sleeping sickness. Administration is subcutaneous.

Antityphoid Inoculation.

A Bill is being presented to the Senate for rendering antityphoid inoculation obligatory for all French citizens. No penalties for failing to comply with the law have so far been provided.

Cabanès has been examining the hereditary characters of the Hapsburg dynasty, which include prognathism, hypertrophy of the nose and lower lip, and acrocephalia. These stigmata, he finds, have been transmitted notably in the direct line, and are more distinct in the males.

Since dealers are not always above suspicion of favouring rises in the price of food-stuffs, legislation is being introduced providing penalties for those who waste food or wilfully allow it to spoil. The penalties provide for fines ranging from 100 to 30,000 francs, and for imprisonment for periods of eight days to three years.

In order to encourage the growing of medicinal plants in France and in the French colonies a cinematograph film has been prepared at the instance of the Minister of Agriculture.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are the 1925 statistics of the City of Liverpool and six counties :—

Name of district	Estimated mid-year population (R.-G.).	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.	
			All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Heart disease.	Infant mortality.	Maternal mort. from childbirth.
Liverpool ..	842,968	23·3	14·1	1·52	1·18	3·5	1·1	99	2·9
Kent	1,110,500	16·5	11·5	0·90	1·43	1·8	1·7	56	2·8
Staffordshire.	722,000	21·0	12·0	0·93	1·09	2·6	1·4	82	3·1
Cheshire ..	645,900	16·0	11·8	0·79	1·33	2·1	1·7	73	4·8
Norfolk ..	322,600	16·7	12·2	0·77	1·73	1·9	1·8	54	2·4
Leicestershire	274,600	17·7	11·4	1·00	1·20	1·9	1·6	71	4·7
Cambridgeshire*	70,270	15·6	12·1	0·78	1·79	1·9	1·9	55	2·7

* Excluding Cambridge borough.

Liverpool.

Dr. A. A. Mussen describes how the Schick test and subsequent immunisation were successfully used to end outbreaks of diphtheria in four residential institutions. The notifications of encephalitis lethargica numbered 108 as compared with 189 in 1924. The deaths, however, were more. Eight of the deaths were those of persons notified in earlier years, but excluding these the case fatality in 1925 was 33·4 per cent. During 1922 and 1923 the choreiform type was prominent, but during 1925 the lethargic type predominated again. Half the cases occurred under 30 years of age, and there were few cases over 60. The fatality increased with advancing age, but the smaller fatality in youth is offset by the liability to develop sequelæ. Cases are cited to indicate the infectious nature of the disease. Thus 17 per cent. of the acute cases in Liverpool during 1925 had a possible connexion with a preceding case. In 1924 and 1923 a similar possible connexion was traced in 17·7 per cent. and 9 per cent. respectively. From the consideration of such groups the incubation period is thought to be from a week to a fortnight. The occurrence of cases in contacts, after five months in two cases and after 20 months and two years in two other cases, indicates the possible duration of infectivity for prolonged periods. Of the 22 cases which occurred among school-children during 1925 two proved fatal, and of the survivors 14 are known to have developed sequelæ. In seven of these the prominent symptom was inversion of the sleep rhythm, in four Parkinsonism, and in three mental deterioration. Dr. Mussen suggests that such survivors should at first be taught in special classes in the schools for physically defective children, but kept quite apart from the other physically defectives. If experience shows such treatment to be unsatisfactory, residential treatment in conjunction with other local authorities may have to be considered. Home contacts are now excluded from school for three weeks.

Five cases of anthrax occurred, with two deaths. Two handled wool in a warehouse, two worked among wool and hides at the docks, and one in a tannery. Fur dermatitis from rabbit skins dyed to resemble beaver is reported to be increasingly common. In the dyeing process an oxidising agent is used, and if oxidation is complete the dyed article is innocuous. The skin irritation caused may be very severe and may become eczematous. At the Fazakerley Hospital success has been obtained in the immunisation of the staff against scarlet fever. The Schultz-Charlton reaction has been in general use since December, 1924, for diagnostic purposes, and the use of specific anti-streptococcus serum in the treatment of scarlet fever appears to give good results. Also passive immunisation by scarlatinal antistreptococcus serum is found to be of value in preventing cross-infection.

A table shows that an increase in the routine veterinary inspections of the city herds reveals more cases of tubercle of the udder. There are 286 city cowsheds, with accommodation for 3870 cows. In 1920, 56 routine inspections discovered six cases of tubercle of the udder, while in 1924 and 1925 there were 697 and 717 inspections, and 26 and 21 tuberculous udders discovered respectively. The city bacteriologist reports that of 172 samples of milk examined for the city hospitals 14 contained the tubercle bacillus, and that seven out of 84 samples from infant welfare centres and 63 out of 586 samples from milkshops, railway stations, &c., were tuberculous. An advance has been made in housing matters by the scheduling of Pitt-street area. A confirming order was made by the Ministry, and the buildings are now being demolished, and plans have been approved for the erection of 57 tenements on the site. Despite the operations of the housing committee and the activity of private builders, who during the last five years have erected 8122 dwellings, there were over 11,000 applications for corporation dwellings on the waiting list at the end of 1925.

Kent.

Dr. Alfred Greenwood describes the growth of the county pathological laboratory, which was established in 1911 with the intention primarily of carrying out simple bacteriological examinations for district medical officers of health. The work has been gradually extended, until at the present time almost every kind of pathological work is done at Maidstone for the medical practitioners of the county. In addition to the ordinary examinations for infectious diseases, the work now includes examinations of urine and pus, histological examination of tissues, tumours, &c., with supply of sections if required, blood examinations, blood counts, blood sugar tests. A whole-time pathologist is employed. During the year ending 1926, 21,784 specimens were reported upon. The charge on the county rate for the laboratory for the year was £1663, and the average cost per examination 1*s.* 6*d.* Dr. Greenwood emphasises the fact that the laboratory has been well worth while

especially in a county like Kent, where there is no university or commercial laboratory available.

The clean milk competition was continued successfully during 1925, and the reports from the districts show the need for it. Little, if any, veterinary inspection of cows appears to be in operation, and only 25 samples of milk were sent to the county laboratory to be tested for tubercle, including one sent on account of a complaint of tuberculous milk from the medical officer of health of the London County Council. The arrangements for the reception of the Kentish hop-pickers are being greatly improved year by year, but there still remains a minority of growers who are not amenable to reason in this matter. The reports from the districts show that many improvements have been made during the last five years in drainage, sewerage, and the prevention of the pollution of rivers. As regards scavenging, however, Dr. Greenwood mentions that among his 42 urban and 23 rural districts it is the exception to have a thoroughly well-organised and up-to-date method of disposal, and that in the majority of the urban districts there is no justification for this. The nuisance from the tipping of London refuse has been lessened in recent years, but several of the rural districts suffer from the deposit of refuse by the Kentish towns. A duel is reported between Southborough and Tunbridge Wells. Southborough deposits its refuse and creates a fly and rat nuisance in Tunbridge Wells. Tunbridge Wells returns the compliment. An amicable arrangement for a joint destructor for these two urban districts may be the result.

Taken as a whole, the housing situation does not improve. Thus the shortage estimated in 1922 at 5554 is estimated in 1925 as 9742.

Staffordshire.

Dr. W. D. Carruthers gives a survey of the position as regards the pollution of rivers. Three-quarters of the county is within the watershed of the Trent. The narrow strip along its north-western border is within the watershed of the Mersey, and further south there is an area draining into the Severn. The Trent and its main tributary, the Tame, are heavily polluted in the industrial areas of the county. The same remark applies to the Stour, which drains into the Severn. The standards recommended by the Royal Commission assume that an effluent will be diluted eight times by river water on its discharge, but this does not occur in the industrial areas of Staffordshire, and Dr. Carruthers urges that a higher standard of purification is, therefore, necessary. He also emphasises the bad effects when the river water is completely held up by a weir, making the basin above the weir practically a septic tank, and interfering with the natural power of recovery. Tables are given showing the percentage of oxygen saturation of the rivers Trent and Stour at various points, which make it clear that these rivers are usually too much polluted to support fish life. Many of the authorities in Staffordshire are quite alive to the situation, and a considerable amount of work has been done, but obviously much more is required.

Building during the last five years has only been sufficient to meet the natural increase of the population. Dr. Carruthers hopes that the new Act, which allows assistance from the public funds for the improvement of existing cottages, will help to find houses for the agricultural workers at something like an economic rent. The county council has not appointed whole-time veterinary surgeons to deal with tuberculous milk, but has allocated this work to the officers appointed under the Diseases of Animals Acts. During 1925 six complaints of tuberculous milk were received from the London County Council, and in each case animals were slaughtered under the Tuberculosis Order. One complaint from Stoke had a negative result. At the end of 1925 there were four licences for the production of Grade A milk. One of these four producers could not comply with the standard, and it was found that his bottles would not stand being put in the steriliser without cracking. Dr. Carruthers points out that two small-pox hospitals would serve the whole county, and that seven others might be abolished. There were 45 cases of encephalitis lethargica and 26 deaths during 1925. About 35 per cent. of the county population are without satisfactory isolation hospital provision. The bacteriological work of the county was transferred from Birmingham University in July, 1922, and a county laboratory has been established at the Wolverhampton General Hospital.

Cheshire.

Dr. Meredith Young states that the greater portion of the county comes within the maternity and child welfare scheme. There are seven county midwives, who are granted an allowance of £60 per annum in addition to the fees which they earn until they have a practice sufficient to support them. Through the enterprise of the county nursing superintendent a Cheshire Midwives Association has been formed, with seven branches, each of which has a series of monthly lectures. The shortage of houses interferes with the character training of children. The mothers who live in rooms say they have to give a child anything it wants to keep it quiet. The shortage of houses is general, but the local authorities are said to be facing the problem in a satisfactory manner. Constant supervision has been maintained over the Dee, Weaver, and Dane, and all these rivers are fit for fish to live in. The greatest difficulty is found with the Dee because of the pollutions which emanate from Wales. In the neighbouring counties of Flint and Denbigh river pollution is regarded with indifference, and the Dee was not long ago associated with an outbreak of typhoid fever. Dr. Young advocates the formation of a joint committee armed with powers similar to those possessed by the Mersey and Irwell Committee. The only industrial waste which gives trouble is ammonium sulphate spent-liquor from collieries. The Cheshire College of Agriculture have done much to encourage clean milk. Dr. Young thinks, however, that the time is ripe for a whole-time veterinary service, and that the recent Milk and Dairies Order will make this step almost obligatory.

Norfolk.

Dr. J. T. C. Nash points out that school medical inspection work is still in a watertight compartment and has not been coördinated with the other public health work. He also advocates the appointment of a deputy medical officer of health and school medical officer. There are practically no factories in the county area, and in the rich fruit-growing land on the west the inhabitants are comparatively well above the poverty line, but the benefit of this is somewhat discounted by mothers leaving their children to go out as land-workers. Women's institutes, largely due to the exertions of Lady Suffield, are a great feature in the village life. Cinemas and wireless have also deeply invaded districts which at the beginning of the century were either "deadly dull" or "unspoilt," according to the particular viewpoint. An outbreak of catarrhal jaundice, affecting many persons, both adults and children, but without a death, appeared to be associated with influenza. Influenza itself was responsible for 181 deaths during the year. As regards isolation hospitals, Dr. Nash has for many years held that in these days of motor transport one central hospital for the whole county would be much the best solution. The county health committee supports this view and had secured a suitable site, but the districts could not agree among themselves. The housing work of the last five years has not met the needs of the agricultural labourers—the class most in need of cottages. A move has been made in the direction of an orthopædic scheme by the appointment of a joint committee.

Leicestershire.

Dr. T. Robinson points out that the present arrangements for treating surgical tuberculosis

are of a temporary nature and insufficient. A joint scheme under the county council and the Leicester City Council is now under consideration. The county council make a grant of £50 to the Leicester and Leicestershire Maternity Hospital, and in return for this sent in six cases during 1925. There are now 37 maternity and child welfare centres operating in the county. During 1925 an exhibition with lectures and demonstrations was held at seven centres. Lectures were given to practising midwives at five centres by Dr. E. L. Lilley, obstetric surgeon to the maternity hospital. The subjects dealt with were chart-keeping, danger signals in pregnancy, and antenatal work.

The county bacteriological laboratory, which was opened in 1919, did more work than ever before in 1925. An extension has been made for the purpose of dealing with bacteriological examinations of milk. The districts are encouraged to send samples, and during 1925 8 of the 12 urban districts and 5 of the 13 rural districts fell in with the scheme; 589 samples were sent in. Of these 320 were classified as good and 143 as bad, 112 being fair and 14 moderate. Of the 320 good samples, 265 came within Grade A standard. During 1926 six more rural districts are taking part in the scheme, which is said to be producing an improvement as regards the production of clean milk. There are 2290 milk producers in the county and 35,000 cows. The Ministry have issued licences for Certified Milk to four producers and for Grade A (tuberculin-tested) to one. The county council have issued Grade A licences to eight producers, one of whom, however, gave up his licence in September owing to adverse reports on his samples. One Grade A producer was unable to comply with the *B. coli* standard, and it was found that his water-supply was unsatisfactory. A fresh water-supply enabled him to comply with the standard.

Cambridgeshire.

Dr. Frank Robinson reports that the county council pay maintenance charges for tuberculous patients at Papworth Colony, and depend upon Addenbrooke's Hospital for the treatment of surgical tuberculosis, for V.D. work, and for maternity beds. A scheme for the provision of a maternity home for the use of the town and county within the curtilage of the last-named hospital was also under consideration during the year. In January, 1906, there were 24 trained and 42 untrained midwives in the county; in January, 1926, there were 50 trained midwives and two untrained. The county council grant nursing scholarships and also subsidise associations employing nurse-midwives. Of the 129 rural parishes there are still 27 with a total population of 9198, for which a midwifery service has not been provided. The provision of light treatment was considered during the year, and it was decided to send lupus cases to the London Hospital for treatment and bone and joint tuberculosis cases to Alton, but it is hoped to have a local out-patient light centre. The county council have taken no action in the matter of tuberculous milk, nor have they received any application from the district councils with regard to this matter. Housing accommodation in the county is still inadequate and closing orders for unfit houses are seldom made.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED DEC. 11TH, 1926.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 328 (last week 316); scarlet fever, 1716; diphtheria, 1185; enteric fever, 49; pneumonia, 1309; puerperal fever, 47; puerperal pyrexia, 124; cerebro-spinal fever 8; acute poliomyelitis, 37; acute polio-encephalitis, 6; encephalitis lethargica, 42; continued fever, 1; dysentery, 4; ophthalmia neonatorum, 124. There was no case of cholera, plague, or typhus fever notified during the week.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 2 (0) from enteric fever, 15 (1) from measles, 8 (3) from scarlet fever, 37 (10) from whooping-cough, 47 (9) from diphtheria, 72 (15) from diarrhœa and enteritis under 2 years, and 52 (18) from influenza. The figures in parentheses are those for London itself.

SCHOOL MEDICAL SERVICE.

Name of district.	No. on roll.	Av. elem. school attendance.	No. of routine children examined.	No. of special examinations and re-inspections.	Percentage of children found on routine examination requiring treatment.*
Cumberland C.C. ..	—†	—†	8,269	15,747	18·0
Wigan ..	13,621	11,836	3,810	7,305	20·0

* Excluding uncleanliness and dental defects. † Not given.

Cumberland.

Dr. F. H. Morrison, in his report for 1925, describes the method of coördinating the health services throughout the county, by which in no case is the full time of any doctor or nurse given to school work alone. The county is divided into six areas, with one medical officer in charge of the whole of the work (except venereal diseases) in each area. This system has obvious advantages, although no one man can be an expert in all branches, with the result that certain conditions may attract less attention than they deserve; it may be for this reason that in Cumberland comparatively few exceptional children have been discovered—e.g., only four blind and seven mental defectives in the whole county. The facilities for dealing with such children are few, but the difficulty in making adequate arrangements in rural areas is very real. This difficulty exists, also, in providing clinics, and the proposed travelling motor-van clinic will be a useful expedient. The dental caravan has been highly successful, as has also the work of the travelling orthopædic nurse. Surgical clogs have been used in the correction of deformities of the feet and legs, and present many advantages in mining districts, where clogs are worn daily by the children. Dr. Kenneth Fraser has carried out a special inquiry into the association of deficiency of iodine with many common conditions met with in school-children. He gives a full account of iodine deficiency and of the prevention and cure of its effects, stating his belief that goitre is only one of these effects. Finally there is a record of 100 children suffering from different diseases such as septic infection, bronchitis, and general debility, whom he treated with iodine with definite improvement in almost every case.

Wigan.

Dr. Henry Whitehead presents his report in a concise and interesting manner. There is direct coördination in Wigan between the child welfare scheme and the school medical service, so that the school medical inspector has the previous history of the child when it first attends school. Dr. Whitehead gives a depressing account of the sanitary conditions of the schools, the majority of which were built prior to 1880, and many were not originally intended as school premises. Heating, lighting, and ventilation are generally bad, while some of the sanitary conveniences constitute definite nuisances. He sums up: "The conditions which exist must have some deleterious effect on the general health of the children." An outline is given of the system employed in the control of infectious diseases, and much extra work has been laid on the staff since every case of chicken-pox (made compulsorily notifiable in 1925 owing to the prevalence of small-pox) is at once visited by a medical officer. Measles was also notifiable during the epidemic at the beginning of 1925, and extra nurses had to be employed to keep pace with the home visiting. Dr. Whitehead has an uphill fight in combating the verminous condition of the Wigan children; "it is deplorable," he writes, "to find a great number of children with verminous heads, again about 17 per cent. of the total inspected." There are at present no open-air schools in the town, nor school baths, nor any provision for the blind or deaf, nor for physically or mentally defective children. It would appear that the Education Committee of

this county borough is scarcely shouldering its statutory duties for the welfare of children.

MENTAL HOSPITAL REPORTS.

The *Derby Borough Mental Hospital* had 484 patients in residence on Dec. 31st, 1925, 70 more than at the beginning of the year, so that the number of vacancies was reduced to 12. The recovery rate was 22·3 per cent. and the death-rate 5·96 per cent., verified by autopsy in 86 per cent. of cases. The general health was good, apart from an epidemic of influenza in the spring and six patients under treatment for tuberculosis. The unused isolation hospital has been refitted for the reception of 16 convalescents or parole patients. Wireless has been installed in all the wards. Only three patients have as yet been allowed out on trial. A dentist visits twice monthly. Six nurses and one attendant obtained their M.P.A. certificate during the year, bringing the total up to 33 per cent. and 59 per cent. respectively.

The *Inverness District Asylum* housed 717 patients at the end of May, 1926, an increase of 27 during the year. The recovery rate was 62·3 per cent., and 15 patients were sent out on trial. Two of them had to return. The death-rate was 8·2 per cent.; 25 deaths were due to senile decay, which, with phthisis, accounted for over half. The farm, gardens, and constructive work, including a new reservoir, provide occupation for a large number of male patients. Eleven beasts were shown at the Farmers' Society Show in August, 1926, and gained 11 prizes and recommendations. A hall of suitable size is being built. For the second year in succession all the entrants for the final M.P.A. examination were successful. Fourteen obtained their certificate.

Institutions for Mental Defectives.

The *Royal Albert Institution for the Feebleminded, Lancaster*, had 805 names on its books on March 31st, 1926, and its financial position remains satisfactory. There were 17 deaths during the year, four from phthisis, 2 from influenza, and one from diphtheria, the source of which could not be found. Among new occupations introduced are art sealing-wax, leather and pewter work, paper-hat and lampshade construction, elementary woodwork, and leather stitching. Twelve school garden plots have been prepared for the inmates to work in. More facilities have been provided for clock golf, and this has been found very steadying for patients with such affections as athetosis and spasmodic tic. It has been decided that recent cases of encephalitis lethargica shall not be admitted, as the superintendent feels that there might be an infectivity risk. The report is illustrated by photographs of the patients at work and play.

The *Derby Borough* Committee for the care of the mentally defective reports continued difficulty in finding accommodation for the urgent cases reported to them. They have 28 patients in the Mental Hospital, costing about £1300 a year. Could these have been placed under the Mental Deficiency Act the cost would have been halved. There were 40 defectives under certificate in institutions on Dec. 31st.

The *Lancashire and Cheshire* Society for the Permanent Care of the Feebleminded maintains a colony with 90 women, 45 girls, 127 men, and 55 boys. Their health during the year has been good; there were two deaths and no infectious disease. The farm and gardens successfully provide occupation for numbers of patients, even including imbeciles. There was a marked improvement in the liveliness and happiness of the school-children last year. The staff have formed themselves into a committee to teach the boys cricket and football, a great improvement on the haphazard games that were previously the rule. Twenty-three acres of land have been added to the society's estate, and it is proposed to alter the farmhouse so as to provide 50 additional places for boys. Every vacancy is filled as it arises, and many applications have to be refused. The report is illustrated with photographs of the buildings and land, and an urgent appeal is made for contributions.

ULTRA-VIOLET RADIATION.

To the Editor of THE LANCET.

SIR,—The excellent results recorded by Dr. Punch and Dr. Wilkinson in your issue of Dec. 11th call for greater detail of the technique they adopted. For general exposures they appear to have used on the same patient both the air-cooled mercury-vapour and the carbon arc. One notes, for instance, that in Case 1, after the first nine exposures with the mercury-vapour lamp, succeeding exposures alternated between the mercury vapour and the carbon arc. What were the indications for changing the apparatus? If the more continuous spectrum of a carbon arc was indicated for one occasion, why was it contra-indicated at the next? It does not appear to have been merely a matter of convenience, for a definite system of changing the lamps was adopted. Do the authors claim any particular advantage for this method? Again, for local treatment to the scar in this case the tungsten arc was used. Was there any particular indication for changing from the mercury-vapour lamps, either of which could have been used for treating the scar? What was the relation of a carbon arc dose to the mercury vapour dose in erythema-producing terms?

Case 3 shows up the dangers of ultra-violet therapy. Conclusions are based on a single case and that not of a very progressive type, nor one in which the anæmia was very striking. There are so many practitioners using ultra-violet radiation that some may also be tempted to rely on ultra-violet rays for the treatment of Hodgkin's disease, to the exclusion of methods such as X rays, which are far more likely to be of benefit. It is not suggested that ultra-violet radiation may not be of benefit for the secondary anæmia, but surely there is no justification as yet for making it the only or even the most important method of treating Hodgkin's disease.

My own experience of ultra-violet radiation in Hodgkin's disease is limited to two cases. One case, owing to the erroneous diagnosis of tuberculous glands (tubercle bacilli had been found in his sputa at a sanatorium) was treated for four months with both local and general ultra-violet radiation. He did not improve, the main mass of glands becoming somewhat larger. A gland was then excised, which showed the case to be one of Hodgkin's disease. The second case was put on ultra-violet treatment, pending X ray treatment. After a month's treatment the patient stated he felt better, but beyond a slight decrease in the size of the spleen there was no clinical evidence of improvement. The patient discharged himself from the hospital then, only to return several months later in a hopeless condition. I feel, therefore, that the value of ultra-violet radiation in Hodgkin's disease still remains to be proved.

I am, Sir, yours faithfully,

London, W., Dec. 16th, 1926. M. WEINBREN.

THE DISSOLUTION OF INSULIN.

To the Editor of THE LANCET.

SIR,—The hyperglycæmic action of insulin is described on pages 122 and 123 of the first volume of "The Nature of Disease," published in 1924. It would appear from further experimentation that the action of insulin is influenced by the state in which the protein particles in the plasma happen to be when the injection is made. The previous administration of certain conductors, such as sup 468, tartrazine, &c., and of certain condensers, such as oxygen, the carbon disulphide product of dimethylamine, &c., prevents insulin from causing hypoglycæmia. The subsequent administration of certain conductors, such as sup 36, and of certain condensers, such as glucose, dihydroxyacetone, &c., prevents fits occur-

ing following a hypoglycæmic dose of insulin and cheeks the fits if they are already in being. The action of these drugs is to increase the number and to diminish the size of the protein particles in the plasma, the effect of which is to raise the percentage of the blood-sugar. The percentage of the blood-sugar is raised because the carbohydrate fraction of the protein particles is less firmly adsorbed. Insulin lowers the percentage of the blood-sugar because it fixes the carbohydrate fraction more firmly to the protein particles. Fits are caused because the protein particles become too big to circulate.

When protein particles increase in size they leave the peripheral circulation to become precipitated in the cerebral capillaries, and it is this precipitation which causes fits, convulsions, coma, and death. The moment the enlarged particles are broken up, or dispersed, and restored to the circulation, the fits cease. The drugs most capable of acting in this way are those with a small nucleus and having one or more of their active groups negatively charged. The reason why fructose, galactose, &c., are of no value in preventing and overcoming insulin intoxication is because the active group in the No. 1 position is not negatively charged. Therefore, glucose does not act by restoring to the blood the sugar insulin has driven away, because insulin does not deplete the blood of sugar; it only makes it become more part and parcel of the protein particles in which state it is not to be detected as sugar.

The complete action of insulin is discussed at full length in both volumes of "The Nature of Disease."

I am, Sir, yours faithfully,

J. E. R. MCDONAGH.

Wimpole-street, W., Dec. 17th, 1926.

GANGRENE OF THE TOE.

To the Editor of THE LANCET.

SIR,—Prof. Gask and Sir John O'Conor have given, in your issue of Dec. 11th, interesting views on the pathology and treatment of this very serious condition. I have under my care at the present moment a case which quite upholds Sir John O'Conor's method of treatment. Twelve months ago I was sent for to see a woman aged 70. She had gangrene of the big toe. The nail and the toe itself were gangrenous up to a line extending round the toe at the level of the root of the nail. No arterial pulsation could be felt at the ankle. The heart was intermittent; the urine crowded with streptococci contained neither sugar nor albumin. Lymphangitis was creeping up the leg to the knee. The patient refused treatment at hospital, where I explained to her she could have her choice between sympathicectomy and diathermy. Prof. Gask's views seem to coincide with those of MM. Lian and Barrieu in the current number of the *Année Médicale Pratique*: "La sympathicectomie, outre qu'elle n'est pas une opération dépourvue de danger, est loin d'avoir enregistré à son actif des succès tels qu'on doive la considérer comme une indication formelle."

The treatment pursued at the patient's home was as follows. The gangrenous foot was placed as often and as long as possible in warm water containing 5 per cent. bicarbonate of soda, the heat of the water being gradually raised to a point just bearable. At night the toe was smeared with warm glycerine and belladonna, and enveloped in cotton-wool. In a month the dead tissue began to lift off the living and what remains of the toe is firmly healed. The patient, who was bedridden, is now able to help in the house work.

Text-books and articles dealing with the condition are unanimous in the opinion that neither sympathicectomy nor diathermy has any appreciable effect on the larger arteries of the limb. The good they do is dependent solely on improvement of the collateral circulation. The treatment which Sir John O'Conor recommends and which I gave my patient had an extremely satisfactory result.

I am, Sir, yours faithfully,

Exeter, Dec. 14th, 1926. J. PEREIRA GRAY.

Obituary.

HUGH CAMPBELL ROSS, M.R.C.S., L.R.C.P. LOND.

Dr. H. C. Ross died at sea on Dec. 14th from hypostatic pneumonia at the early age of 51. He was one of three distinguished medical brothers, sons of General Sir Campbell Ross, K.C.B., the others being Sir Ronald Ross, F.R.S., and Dr. E. Halford Ross, to whom we extend our sympathy. Educated at the Isle of Wight College and St. Thomas's Hospital, Hugh C. Ross took his medical qualification in 1898 and held posts as house surgeon and house physician at the West London Hospital. During the South African war he served as a civil surgeon in the South African Field Force and after peace was declared joined the Royal Naval Medical Service for four years. From 1906 to 1908 he was a medical officer in the public health department of Egypt, where he inaugurated an antimosquito campaign. On his return to this country he went to Liverpool, where, as director of cancer research attached to the Royal Southern Hospital, he studied problems of cell-division in relation to cancer and published, jointly with Dr. J. W. Cropper, a book entitled "Induced Cell-reproduction and Cancer" which caused some controversy. In 1910 Dr. Ross moved to London as director of a research organisation financed by Mr. J. H. McFadden, of Philadelphia, the laboratories of which were housed in the building of the Lister Institute. For six years Mr. McFadden continued to support this organisation, which was originally founded for research in cancer, but later extended to work on other problems. During this period investigations were made under the direction of Dr. Ross into the cause of cancer in certain occupations, and his own interests broadened to include industrial diseases of all kinds, especially silicosis. During the war Dr. Ross worked in the clinical laboratory of the Ministry of National Service. He was a man of catholic interests and a wide experience; his views were often unorthodox but always stimulating, and his early death will be regretted by many friends and colleagues.

HENRY ROSS TODD, F.R.C.S. IREL.

THE sudden death of Dr. H. R. Todd on Dec. 16th removes a man who brought a gifted personality to the practice of medicine. He was the son of Robert Ross Todd, of Dublin, Clerk of the Crown and Peace for County Down, and was born in 1862. Qualifying in 1883, he worked for a time as resident medical officer and registrar at the Cork-street Fever Hospital, and then settled at Warlingham, where his practice was large and successful. In 1900 he became a Fellow of the Royal College of Surgeons in Ireland, and in the following year left Warlingham to take up work in the West-end of London. The number of his patients began to grow rapidly, but after only a year in London, for reasons connected with the health of his family, Dr. Todd decided to retire. He was still a comparatively young man, and he bought a very small practice at Bembridge, in the Isle of Wight, anticipating that a couple of hours' work each morning would be all that was necessary, and that this time would be devoted to the poor. His reputation, however, increased so rapidly that he soon found he had more work than he wished for. He therefore determined to give up work altogether, and went to live at Ipsden, in the Chilterns. But many old patients went on consulting him about their difficulties; he gradually became more interested in the mental side of disease, and finally he came back to London, where he treated patients for phobias, bad habits, and nervous instability. "Although Dr. Todd had no profound knowledge of the later scientific developments in medicine," writes a colleague, "he had a keen and accurate diagnostic sense. With this he possessed an almost uncanny power of knowing what his patient was thinking and feeling, an immense power of

sympathy, a level-headed appreciation of the relative value of things, a happy optimism, and great tact." As a result he had the power of inspiring immediate confidence, and where other people could be helped he spared neither time nor trouble.

Dr. Todd had been suffering from myocardial disease for some time, and died when travelling in the train from London to his home at Aston Clinton. He leaves a widow, a married daughter, and two grandchildren.

LAURA WILLIAMS PUGH, M.B. EDIN., D.P.H.

Dr. Laura Pugh, medical officer of the Welsh Board of Health (Ministry of Health), died at her home at Machynlleth on Dec. 17th. She was the sister of the late Dr. Robert Pugh, medical superintendent of the Joint Counties Asylum, Talgarth, and received her medical education at Birmingham and Edinburgh, graduating in 1908. Later she obtained the D.P.H. of the English Conjoint Board. After some years' service as assistant medical officer at the West Ham Union Infirmary she returned to Wales in 1914 to enter the service of the Monmouthshire County Council as assistant school medical officer and medical officer in charge of the maternity and child welfare centres of the county. She became an approved lecturer under the Central Midwives Board, and in that capacity delivered courses of lectures to midwives at the Tredegar Maternity Home. Three years ago she was appointed by the Minister of Health to be the woman medical officer of the Welsh Board of Health, her duties including the inspection of maternity and child welfare schemes and maternity hospitals throughout Wales.

Dr. Pugh was a very capable officer and soon became popular with officials of local authorities with whom she came in contact. She was a woman of strong character, and during her short period of office succeeded in effecting great improvements in maternity and child welfare work in Wales. In February of this year she entered a nursing home in London to undergo an operation, but she was found to be suffering from malignant disease for which no relief could be given. After a short period of rest she returned to her duties and with characteristic courage carried on her work until last month.

"Dr. Pugh was devoted to her work," writes a colleague. "Though she well knew that the end was inevitable and could not be long delayed, she resolutely remained at her post until further work was physically impossible. She never thought of herself but was always anxious to be of service to others. She was one of the most delightful and loyal of colleagues and will be greatly missed by those with whom she worked at the Welsh Board of Health and by the medical officials of local authorities in Wales."

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—The Prince of Wales's General Hospital will hold an intensive course in general medicine, surgery, and the specialties from Jan. 10th to 22nd, the daily sessions will be from 10.30 A.M. to 5.30 P.M., and the formal lectures at 4.30 P.M. will be open to members of the Fellowship of Medicine. Beginning on Jan. 10th there will be a two weeks' course in Diseases of Children at the Royal Free Hospital and at the Children's Clinic. At the Bethlem Royal Hospital, from Jan. 11th to Feb. 5th, a series of lecture-demonstrations on psychological medicine will be undertaken by Dr. Porter Phillips and the members of his staff on Tuesdays and Saturdays at 11 A.M. The National Hospital for Diseases of the Heart will hold a course in cardiology from Jan. 17th to 29th. Early application is desirable as the entry is limited to 20. Courses in obstetrics are arranged at the Queen Charlotte's Hospital and the City of London Maternity Hospital; personal application must be made to the Fellowship, which can also make arrangements for the appointment of clinical assistants at the Samaritan Hospital for Women. The series of lectures, arranged by the Fellowship, on Emergencies in Medicine and Surgery, will recommence on Jan. 27th. Clinical demonstrations in surgery and ophthalmology have also been arranged to start in January. Syllabuses of the special courses and copies of the programme of the general course and of the *Post-Graduate Medical Journal* may be had from the Secretary of the Fellowship at 1, Wimpole-street, London, W. 1.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The End of the Session.

PARLIAMENT was prorogued on Wednesday, Dec. 15th, until Feb. 8th, 1927. The King's Speech, which was read by the Lord Chancellor in the House of Lords, commented on the fact that the improvement in housing accommodation continued. A larger number of new houses had been completed than in any previous year. Among the Acts to which the Royal Assent was given by Commission were: The Lead Paint (Protection against Poisoning) Act; the Workmen's Compensation Act, 1926; the Public Health (Smoke Abatement) Act; the University of London Act; the Births and Deaths Registration Act; the Housing (Rural Workers) Act; and the Coroners (Amendment) Act.

HOUSE OF COMMONS.

TUESDAY, DEC. 14TH.

Government and the Necessitous Areas.

ON the motion for the adjournment of the House,

Mr. W. GRAHAM called attention to the enormous growth of the liabilities of the local authorities due to industrial distress within recent years. He said that he did not suggest that any Government had been free from difficulty in this matter, and it would be idle to deny that a considerable sum of public money was involved. But in view of the fact that they were at the end of four or five years of industrial depression, and that events had been aggravated very much by the circumstances of 1926, it was possible to show that the case for the local authorities had become urgent and indeed overwhelming. Recent figures had shown that the amount of out-relief in England and Wales, which was £2,000,000 to £3,000,000 annually under normal pre-war conditions, had risen as high as £15,000,000 or £16,000,000. He suggested that even if they took the most optimistic view of industrial recovery in this country in the near future, several of these local authorities were going to find it almost impossible, if not indeed impossible, to meet the liabilities which surrounded them. The great bulk of the members of the Labour Party had come to the conclusion that it was only on the basis of some definite State contribution, or the shouldering by the State of some part of the responsibility, that this situation could be met. They all recognised that these very heavy burdens on the localities imposed a load upon industrial recovery which was far less defensible than the load which was imposed by Imperial taxation. If that was the case, they had a very strong argument from the standpoint of industrial recovery for a transference of at least a portion of the burden. Of the evidence tendered to the Meston Committee, 85 per cent. was in favour of a retention of the system of percentage grants. Those grants were broadly and generally 50 per cent. of approved expenditure for purposes of health and education; 75 per cent. for venereal disease treatment; 100 per cent. for certain port sanitary services dealing with the danger of infection, and various percentages in respect of certain other classes and grants. That system had been in force for a number of years in this country, and it was designed to minister to what were believed to be inevitably expanding needs in the community, and to supply on the one side a certain centralised regulation of the work of the local authorities, and on the other side to encourage the local authorities, and on some occasions to press them to undertake those services by the promise that 50 per cent., or some other percentage of the approved expenditure, would be met. Evidence was also tendered to the Meston Committee in favour of block or fixed grants, but that evidence was a very small part of the case submitted to the Committee, and the extraordinary thing was that the draft report—he was obliged to make this public—was inconsistent with the great bulk of the evidence rendered to the Committee.

Sir KINGSLEY WOOD: There never was a report.

Mr. GRAHAM said that he was referring to the draft report of the Chairman. The Government were proceeding with a system of block grants, and apparently proposed to weigh the contribution to the local authorities in terms of extra population, and with reference to assessable value below the country's average. So they were entitled to place these two facts together—namely, the refusal of any specific provision for the necessitous areas, with all their existing needs, and the prospect of some fixed or overhead grant for the future which would amount to nothing more in practice than a rearrangement of the liability or burden year by year within the local authorities themselves; in other words, the State had not stepped in in any capacity to help the local burdens arising from the industrial conditions of the past four or five years. Moreover, it must be

added that the tendency of a great deal of the Government's legislation within recent times had undoubtedly been to increase the burdens upon local authorities. He begged the House not only to give their support for some immediate relief for the necessitous areas, but further to safeguard the future position, for by refusal to assent to a scheme of block grants which was premature could only add to the burdens of the localities, and further penalise the industrial recovery, which he trusted it was their common purpose to promote.

After some discussion,

Mr. NEVILLE CHAMBERLAIN (Minister of Health) said that Mr. Graham devoted part of his speech to the discussion of a report which had never been made by the Meston Committee, and in another part he criticised proposals which the Government had not yet formulated. There seemed to be a good deal about the debate which was shadowy and unreal. There were a good many circumstances which should be taken into account before the Government decided whether anything was necessary to be done in the way of further assistance, and if anything was necessary, what should be done, and in what proportions. He had examined just casually the position in some unions where the distress had been greatest, and he found that on the whole they were not so bad as one might naturally have expected. For instance, he found that in a number of unions the total indebtedness could be wiped off by an extra rate of 2*d.* in the £. In others it amounted to more—up to 2*s.* There were four which were over 10*s.*, one over 15*s.*, and one which was over 32*s.* In Bedwellty an extra rate of 32*s.* 10*d.* would be necessary to wipe off the indebtedness. The position of Bedwellty was being inquired into by one of his inspectors. He would not pass any judgment on it until he got the inspector's report, but he was bound to say that considerable irregularities had been taking place there. There were other differences between one union and another. By some unions relief had been given on loan. In those cases the burdens on the ratepayers would be very materially decreased as the loans were paid off. The time had not come when it was possible to consider what course it might be necessary to take arising out of the special circumstances of the coal stoppage. Guardians were for the present being financed by Goschen loans. They had not fixed a time for repayment, and the position would be reviewed next February. Then they would be able to see what relief it would be still necessary to give in relation to the coal areas. With regard to the permanent difficulty about necessitous areas, that, he believed, was capable of solution not by special grants founded upon temporary circumstances, but by perhaps a better allocation of the burdens as between unemployment insurance on the one side and the Poor-law authorities on the other.

WEDNESDAY, DEC. 15TH.

Fatal Accidents in the Royal Air Force.

Mr. DAY asked the Secretary of State for Air the number of officers and men of the Royal Air Force killed in flying accidents during each of the three years preceding the last convenient date, together with the number of fatal accidents in the French air force during the same period.—Sir S. HOARE replied: The figures as regards the Royal Air Force during the 12 months ending Dec. 9th in each of the years named were as follows: 1926—46 officers, 2 cadets, 28 airmen; 1925—40 officers and 11 airmen; 1924—48 officers, 1 cadet, and 23 airmen. In addition, the following naval, military, or civilian personnel were involved in fatal accidents to Royal Air Force machines: in 1926, 7; 1925, 4; 1924, 2. As regards the French air force, according to my information, statistics of the number of fatal accidents are not made public by the French authorities. I may say, however, that in the course of a debate in the Chamber at the end of November it was stated that there had been 13 fatal accidents in the French military air service on a single type of machine in the space of two months. Whilst this, no doubt, represents an exceptional period such as all air services must experience from time to time, it is apparent from this fact and other confidential information in my possession that figures which have recently been cited in this House purporting to suggest that the accident-rate in France has, during the past two or three years, been more favourable than in this country, are totally inaccurate.

Captain GARRO-JONES asked the Secretary of State for Air if he could conveniently state the proportion of firing accidents incurred by officer pilots and by airmen pilots, respectively, relative to their numbers and hours flown.—Sir S. HOARE replied: Airmen pilots have not been in existence sufficiently long or in sufficiently large numbers to afford a comparison of any value. Broadly speaking, the death-rate amongst airmen pilots has been higher than amongst officer pilots, but it must be remembered that the number of the former is about a tenth the number of the latter, and that one accident makes a considerable difference in the average in so far as the airmen pilots are concerned.

Medical Men and Old Age Pension Vouchers.

Mr. WALTER BAKER asked the Minister of Health whether he was aware of the new regulation whereby an invalid old age pensioner was required to have his or her signature in the book of vouchers witnessed by a minister of religion or a doctor, in addition to possessing the official document certifying inability to apply for payment in person; whether he was aware that old persons who were not on the visiting list of ministers of religion were compelled to pay a doctor's fee in order to obtain the necessary signature; and whether, seeing that the new regulation had been introduced as an official economy, he would increase the number of classes from which a competent witness might be drawn.—Mr. R. MCNEILL (Financial Secretary to the Treasury) replied: Arrangements are under consideration which will remove the inconvenience to which the hon. Member refers.

Lotteries for Hospitals.

Sir CLEMENT KINLOCH-COOKE asked the Secretary of State for the Home Department whether, in view of the increasing difficulty of maintaining hospitals and other charitable institutions, he would consider so amending the Lottery Acts as to make it possible for this method of obtaining funds to be utilised, subject to official sanction, for the collection of money to be used exclusively for such undertakings without the management incurring the risk of a prosecution for acting contrary to law.—Captain HACKING replied: I am afraid my right hon. friend could not undertake to introduce legislation of the kind suggested. Apart from other considerations, he could not propose to cast upon any department or official the duty of giving or withholding sanction.

The Spahlinger Treatment.

Sir CHARLES CAYZER asked the Minister of Health whether local authorities were encouraged to make use of the Spahlinger treatment for tuberculosis; whether this was one of the special benefits on which insurance societies could apply their surpluses; and whether any estimate could be given of the sum of money needed to introduce the system of treatment on an extended scale in this country.—Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) replied: So far as my right hon. friend is aware, the position in regard to this treatment has not changed since I answered a question on this subject on April 27th, and the materials necessary for a scientific investigation of the treatment in this country have not been forthcoming.

Sickness among Civil Servants.

Mr. PRESTON asked the Secretary of the Treasury the total number of sick-leave absences and their average duration among male and female established civil servants outside the Post Office during each of the last five convenient years.—Mr. R. MCNEILL replied: No complete particulars are available as regards the total number of sick-leave absences and their average duration amongst male and female established civil servants in all departments of State, other than the Post Office, during each of the last five years. The following statement, which has been compiled from the records for the last four years of nine principal departments other than the Post Office, may, however, be of interest to my right hon. friend:—

Average Amount of Sick Leave Absence in Days of Established Civil Servants Employed in Nine Principal Departments of State (Exclusive in some cases of Ex-headquarters Staff).

	Men.		Women.
	Disabled.	Others.	
1922	9·6 ..	7·4 ..	12·8
1923	9·9 ..	7·1 ..	13·9
1924	10·6 ..	7·7 ..	14·1
1925	10·5 ..	7·7 ..	14·2

For 1925 the figures are inclusive of Sundays occurring within a period of sick leave; in the earlier years the figures for some departments were for working days only.

Use of Brynite as Meat Preservative.

Lord APSLEY asked the Minister of Health whether brynite was a permitted preservative under the new preservatives order; whether his department had received any complaints of the effect of this preservative on human beings; whether he was aware that animals had succumbed after eating meat so treated; and whether he was satisfied that under no circumstances could brynite be regarded as dangerous to public health when used in connexion with meat.—Mr. NEVILLE CHAMBERLAIN replied: The article mentioned is a proprietary preservative, and according to the information as to its composition which has been given to my department by the proprietors, its use will be permissible in sausages and sausage meat, which are the only meat preparation in which any kind of preservatives will be allowed when the new Regulations become operative. The Departmental Committee on Preservatives in Food reported that the use of preservatives generally is undesirable

and should be restricted as far as possible, but I have not received any special complaints of the effect of this particular article on human beings or on animals.

Regional Dental Officers.

Lieut.-Colonel Sir FREDERICK HALL asked the Minister of Health whether it was proposed to appoint regional dental officers in connexion with dental benefit treatment as administered by approved societies; whether it was intended that these appointments should be held only by registered dentists possessing a diploma recognised and registrable in this country; and, if not, whether he would give an assurance that practitioners holding these registered diplomas would not come under the supervision of any regional dental officer not possessing these diplomas.—Sir KINGSLEY WOOD replied: The answer to the first part of the question is in the affirmative. Applications for the posts have been invited by advertisement, which does not restrict applications to dentists holding any particular diploma. A Selection Committee has been set up, and while no appointments have yet been made, my hon. and gallant friend may rest assured that every attention will be given to the considerations mentioned in the last part of his question.

Medical News.

UNIVERSITY OF OXFORD.—At a Congregation held on Dec. 17th the degree of Doctor of Medicine was conferred on David Thomas Barnes.

UNIVERSITY OF CAMBRIDGE.—At Congregations held on Dec. 10th and 18th, the following degrees were conferred:—

M.B. and B.Ch.—J. M. Dobie, H. H. Fisher, J. Holmes, E. W. P. Thomas, and W. Richards.
M.B.—C. J. P. Grosvenor, G. W. S. de Jersey, C. G. Taylor, and H. M. Woodman.
B.Ch.—W. S. Hunt.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the Primary Examination for the Fellowship, held from Dec. 7th to 18th, 175 candidates presented themselves, of whom 49 were approved and 126 were rejected. The following are the names and medical schools of the successful candidates:—

V. M. Albuquerque, Middlesex; E. F. Barnardo, Cardiff and London; J. C. Barrett, St. Thomas's; C. V. Bloom, London; A. M. Boyd, St. Bart.'s; W. H. Bremner, Otago and Middlesex; E. C. B. Butler, London; W. S. Chapman, St. Mary's; B. Chaudhuri, Bombay and Middlesex; W. W. Craner, London; J. Crooks, Edinburgh; L. Dass, Punjab and Middlesex; H. I. Deitch, Middlesex; A. D. Everett, St. Bart.'s; J. Fitzsimons, Otago and Middlesex; P. H. Fox, Cambridge and St. Bart.'s; A. C. Gairdner, Oxford and London; J. M. Gibson, Oxford and St. Thomas's; Winifred M. Gray, Royal Free; W. P. Greenwood, St. Bart.'s; C. M. Gwillim, St. Bart.'s and St Mary's; K. W. D. Hartley and T. H. Hobbes, St. Bart.'s; F. W. Holdsworth, Cambridge; M. K. Hussein, Cairo and St. Bart.'s; H. P. Hutchinson, Cambridge and St. Bart.'s; B. G. Johnston, Adelaide and London; A. L. Kerr, Liverpool; L. E. Le Souef, Melbourne and Middlesex; O. V. Lloyd-Davies, Middlesex; J. S. Loughridge, Belfast; T. K. S. Lyle, Cambridge and King's Coll.; J. McFadzean, Glasgow and London; G. K. McKee, St. Bart.'s; G. H. Morley, Middlesex; Eileen S. Morris, University Coll.; M. G. Nimatallah, Cairo and London; M. V. P. Peiris, Ceylon and Middlesex; A. S. Philps, St. Bart.'s; R. Purvis, St. Thomas's; R. S. Pyrah, Leeds; L. A. Richardson, Cambridge and St. Thomas's; W. M. Robb, Edinburgh and St. Mary's; G. L. Robinson, Cambridge and London; E. M. Sharples, St. Bart.'s; H. T. Simmons, Manchester; J. F. Simpson, St. Mary's; V. C. Thompson, Cardiff and St. Bart.'s; and J. M. Yoffey, Manchester.

UNIVERSITY OF BIRMINGHAM.—At a Congregation held on Dec. 17th, the following degrees were conferred:—

DOCTOR OF MEDICINE.

Gilbert Henly and Dorothy Jeyes.

BACHELOR OF MEDICINE AND BACHELOR OF SURGERY.

Edna E. Adams, Florence I. Beech, Nagib Gindi, Nagib Iskander, Louise A. Johnson, Chandra Mani, Reginald Nicklin, George R. Orchard, Hubert A. Picton, Hilda H. Reeves, Kamil Rophaeel, Frederick J. Swinton-Esher, and Percy Symons.

UNIVERSITY OF DURHAM: *Faculty of Medicine.*—At examinations held recently, the following candidates were successful:—

THIRD EXAMINATION FOR THE DEGREES OF BACHELOR OF MEDICINE AND BACHELOR OF SURGERY.

Pathology and Bacteriology; Materia Medica, Pharmacology and Pharmacy; Public Health; Medical Jurisprudence.—Gerald Kahn, James C. V. Hindhaugh, and James H. Hudson.
Pathology and Bacteriology; Materia Medica, Pharmacology, General Principles of Therapeutics, and Pharmacy; Public Health; Medical Jurisprudence.—Mohammad Abdul Gaffar.

UNIVERSITY OF LIVERPOOL.—At examinations held recently, the following candidates were successful:—

M.D.

A. R. D. Adams, C. Cookson, F. Earlam, and T. Hare.

M.CH. ORTH.

R. W. Jones, B. L. McFarland, and M. M. Riad.

FINAL EXAMINATION FOR M.B. AND CH.B.

Part III.—H. W. Altschul, H. E. Barrow, G. S. Clouston, W. A. Davies, K. Edmundson, R. W. Eldridge, A. B. Follows, E. E. Glenton, Catherine E. I. Greenshields, J. Hallam, Elizabeth M. Harding, W. E. Hargreaves, Mary Hope-Simpson, E. Hulme, J. Katz, M. A. Lombard, S. G. Massey-Lynch, S. A. Walker, and Joan Watkins.
Part II.—A. E. Adams, Gladys A. Coventry, A. W. Green, J. G. Hattingh, R. E. Jackson, Edna Morris, G. W. Phillips, J. L Walker, and J. Williamson.
Part I.—S. Alstead, *E. T. Bates, S. Canter, H. F. Cohen, *T. B. Davie, Ariel R. S. Deacon, T. L. Dowell, R. J. Doyle, Ruth M. Fennell, J. H. Follows, Agnes G. Gillespie, R. G. Gornall, J. J. Graham, G. T. Harris, W. E. J. Jones, *T. Lasker, N. R. Lawrie, J. M. Leggate, H. Leiper, C. T. Mercer, Doris Morrison, Winifred O'Callaghan, J. Pasvolsky, H. Paterson, E. E. Prebble, E. L. Rubin, M. Silverstone, *H. W. Smith, and G. G. Warburton.

* With distinction.

DIPLOMA IN TROPICAL MEDICINE.

T. A. Austin, W. W. Besson, J. McP. Campbell (recommended for Milne Medal), H. A. A. Doherty, J. C. St.G. Earl, Beatrice N. Fletcher, J. Hamilton, J. H. Kennedy, L. D. Khatri, C. F. McConn, K. L. Malhautra, S. L. A. Manuwa, Winifred H. Mitchell, W. S. Ormiston, F. L. Patterson, V. Puri, A. Robertson, J. G. S. Turner, C. Voigt, and S. N. Wasti.

UNIVERSITY OF EDINBURGH.—At a graduation ceremonial held on Dec. 17th, the following degrees were conferred:—

DOCTOR OF MEDICINE.

†Jessie Gordon, Margaret H. Gordon, Richard T. F. Grace, William T. Graham (in absentia), Arnold A. Hamilton †Kombur Ramaswamy Krishnaswamy Iyengar (in absentia), Edward W. Kirk (in absentia), John H. D. Lawrie, John R. Lord, †John S. MacGill, Duncan Macmillan (in absentia), Dorothea J. Mann, Paul S. Meiring, William G. Patterson, *Eric H. Ponder, William A. Simpson, Arthur F. Smith, George Somerville, John P. Steel, and †Isabel G. H. Wilson.

*Awarded gold medal for thesis.
† Commended for thesis.

BACHELOR OF MEDICINE AND BACHELOR OF SURGERY.

Hussein El. Sayyed Abaza, John D. Ackermann, Aziz Ahmed, James B. Annan, Thomas W. Banks, Francis W. Clark, Alexander R. Cowan, Ian R. Duthie, Vedanayagam Dyream, William D. Forsyth, Evan H. Griffiths, Euphemia T. Guild, Janet W. Jackson, Eva G. John, Isabella M. Marshall, Eugene P. L. L. Masson, William H. Moore, Katherine M. Muirhead, Kiriti Bhusan Mukerjee, George Nahapiet, James G. Paul, Maurice R. J. Peters, Frederick W. Pringle, William H. Rees, Janet C. Ronaldson, Roma M. Ross, Gordon A. Ryrie, Jaswant Singh, Marie Steven, Finlay Sutherland, Winifred E. Wall, and Marjorie S. Waterston.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—At a meeting of the College held on Dec. 15th, Dr. A. Logan Turner, President, in the chair, the following candidates, who passed the requisite examinations between Sept. 27th and Oct. 4th, were admitted Fellows:—

David Band, Conrad G. H. Blakemore, William S. Burr, Palathinkal Varkey Cherian, George R. Davidson, James K. Davidson, Robert Dick, Hubert H. Fisher, Ada Furniss, John J. Gearin, Cassidy de Wet Gibb, Ion S. Hall, Allan Hopkins, James S. Hovell, David Hyslop, David S. M. Jones, Clifford D. Kennedy, Francis Kennedy, Harry S. Kenrick, Henry Aung Khin, Issac Theogarajah Kunaratnam, Reginald H. Lucas, Andrew W. McCay, John I. Noble, Robert D. Owen, John R. Paterson, Charles E. Scott, Cedric H. Swanton, Alan A. Tennent, Raphael Thurse, and James W. Dawson.

JOINT TUBERCULOSIS COUNCIL.—At the last meeting of the Council, held at 1, Upper Montague-street, London, W. 1, Sir Henry Gauvain, who presided, and Prof. S. Lyle Cummins gave an account of their visit to America in connexion with the International Tuberculosis Conference held at Washington. Dr. Varrier Jones and Dr. Nathan Raw had also attended this conference. All were cordially received, and spoke in the warmest terms of the hospitality they had experienced. Sir Henry Gauvain delivered over 50 lectures in Canada and the United States. He had been impressed by the genius for organisation manifested throughout America in business concerns as well as in medicine, of which the Mayo Institute provided a magnificent example in surgery. Operative treatment in surgical tuberculosis was preferred to the conservative measures advocated in this country. The Albee School aimed at internal splinting by bone grafts, while Hibbs and his disciples sought the same end by synostosing the parts affected. The joints of diseased spines were removed, and in hip disease bony ankylosis of femur and ilium was secured. Light treatment was largely employed, and at the J. N. Allen Memorial Hospital Dr.

Brian had invented a lamp reproducing all the rays found in natural sunlight, which had been installed at a cost of $17,000. The same hospital provided for the amusement of patients a private zoo stocked by exacting from every wild beast show exhibiting in the town a toll of one animal. Generally speaking, the mercury-vapour lamp was preferred to the carbon arc. Prof. Cummins spoke of Dr. Lawrason Brown's work, and of the value he attached to light treatment in cases of intestinal ulceration; in this everything depended on the reliability of the X ray diagnosis. Sir Henry Gauvain was renominated chairman of the Council for 1927; Dr. G. Lissant Cox, vice-chairman; Dr. E. Ward, secretary; and Dr. J. Watt, treasurer. It was decided to circulate the employment report to medical officers of health, tuberculosis officers and medical superintendents. It was reported that a successful course in surgical tuberculosis had been held at Heatherwood Hospital, attended by five post-graduates. One tuberculosis worker had taken a course in artificial pneumothorax at the East Anglian Sanatorium. It was decided that a Copenhagen course should find place in the programme for 1927. The next meeting of the Council was arranged for Saturday, Jan. 15th, at 10 A.M.

POPLAR HOSPITAL FOR ACCIDENTS.—At the annual festival it was stated that the hospital now treats 1000 patients a week, and that the reconstruction, which will have cost £80,000, will be completed next year.

WARMING OF LONDON HOSPITAL.—The whole of the boilers and heating arrangements have been condemned, and need to be renewed immediately at a cost of £23,000. At present Lord Knutsford says, the hospital does not possess "as many pence."

WESTON-SUPER-MARE HOSPITAL.—This institution is being enlarged, reconstructed, and modernised at a cost of £50,000 as a memorial of Queen Alexandra. There will be four main wards, each containing 14 beds, and a maternity block, while a number of private beds are being provided.

METROPOLITAN HOSPITAL SUNDAY FUND.—The year's collections amounted to £87,049, a drop of £7792 on last year. Places of worship raised £37,920, which, like donations, was a substantial fall. The working expenses were 4·17 per cent. of the gross receipts, and £80,000 has been distributed.

REGIONAL DENTAL OFFICERS UNDER INSURANCE ACTS.—It is reported that the Minister of Health has decided to appoint six whole-time regional dental officers for England and Wales at a salary of £900 a year. The duty of these officers will be to ensure the efficiency of dental treatment given as an additional benefit under the National Insurance Act.

BRITISH CHARITIES ASSOCIATION.—Presiding at the third annual meeting of the Association, Lord Knutsford reported that the grants made during the year amounted to £76,700—an increase of £46,000 over the previous year. Hospitals beyond the London area received £45,000, King Edward's Hospital Fund for London received £20,000 and the League of Mercy £5000. Distributions for the current year, including a further £15,000 to King Edward's Fund, brought the total distributions up to £148,000. This worked out at the equivalent of a continuous distribution of over £800 per week throughout the three and a half years covering the Association's activities.

THE LANCET: SUBSCRIPTION RATES.

INLAND	One Year	£2	2	0

Appointments.

BROWN, H. G., M.D., C.M. Edin., has been appointed Medical Officer for the Ronnoch Landward area.

DAWSON, W. S., M.D., B.Ch. Oxf., D.P.M., Professor of Psychiatry at Sydney University, Australia.

FITZGIBBON, GIBBON, M.D. Dubl., F.R.C.P.I., Gynæcologist to Mercer's Hospital.

MCCONNELL, A., F.R.C.S.I., appointed to the Chair of Surgery to the School of the Royal College of Surgeons, Ireland.

PAUL, H., M.D., B.Ch. Belf., Medical Officer of Health for Smethwick.

STANNUS, HUGH S., M.D. Lond., M.R.C.P. Lond., D.T.M. & H. Examiner in Tropical Medicine, University of Liverpool.

Certifying Surgeons under the Factory and Workshop Acts, HAMILTON, G., M.B., B.S. Lond. (Chichester): AIRD, A. W., Jun., M.B., Ch.B. Glasg. (Newmilns District of the County of Ayr).

Vacancies.

For further information refer to the advertisement columns.

Bedford County Hospital.—Asst. H.S. At rate of £130.
Calcutta Corporation.—Health Officer. Rs.1500 per mensem.
Charing Cross Hospital, W.C.—Med. Reg. £150.
Dagenham Urban District Council.—M.O.H. and Asst. County M.O. £550 and £250 respectively.
Exeter, Royal Devon and Exeter Hospital.—Sen. H.S. £210.
Greenwich Metropolitan Borough.—Obstet. Consultants. 3 to 5 guineas per consultation.
Hove, Carr-Burton Memorial Hospital, Sackville-road.—Res. M.O. £150.
Hull Royal Infirmary.—Asst. H.S. £150.
Hyde Borough.—Part-time Asst. M.O.H. £300.
Infants Hospital, Vincent-square, Westminster.—Asst. P.
Italian Hospital, Queen-square, W.C.—Asst. Anæsthetist,
London Female Lock Hospital, 283, Harrow-road, W.—First H.S. At rate of £200. Also Second H.S. At rate of £150.
London Temperance Hospital, Hampstead-road, N.W.—H.P. At rate of £100.
Norwich, Norfolk and Norwich Hospital.—Hon. Radiologist.
Oldham, County Borough of.—Asst. M.O. and Asst. Tub. O. £750.
Penn, Bucks, Homerton Residential School for Deaf Children.—M.O. £40 10*s.* plus 11*s.* a head for attendance.
Plaistow Fever Hospital.—Second Asst. M.O. £400.
Prince of Wales's General Hospital, Tottenham, N.—Hon. Asst. Radiologist, Physio-Therapeutist. Also Hon. Asst. S.
Richmond, Surrey, Royal Hospital.—Hon. S. to Out-patients. Also Jun. H.S. At rate of £100.
Royal Army Medical Corps.—Commissions.
Salford Education Committee.—Asst. School M.O. £600.
Ventnor, Isle of Wight, Royal National Hospital for Consumption and Diseases of the Chest.—Jun. Res. M.O. At rate of £300.
West London Hospital, Hammersmith, W.—Hon. S. to Throat, Nose, and Ear Dept. Also Hon. Obstet. Reg.
Worcestershire County Council.—Asst. County M.O. £600.

The Chief Inspector of Factories announces vacant appointments for Certifying Factory Surgeons at Farnham (Surrey), Stock (Essex), and Downham Market (Norfolk).

Births, Marriages, and Deaths.

BIRTHS.

LAIRD.—On Dec. 15th, at Milestone House, Blackwater, Hants, the wife of D. A. Laird, F.R.C.S.E., of a son.

MILLIGAN.—On Dec. 13th, the wife of Norman Milligan, M.B., of a daughter.

DEATHS.

BOOTH.—On Dec. 17th, suddenly, at Marine-parade, Worthing, Lionel Booth, M.D., aged 85.

DAVY.—On Dec. 20th, suddenly, at West End-lane, N.W., William Bradshaw Davy, M.R.C.S., L.R.C.P.

DOIDGE.—On Friday, Dec. 17th, at Kylemore, Glastonbury, Maurice John Doidge, M.D., aged 67.

TODD.—On Dec. 16th, of heart failure, Henry Ross Todd, F.R.C.S.I. and L.R.C.P.I., of The Rookery, Aston Clinton, and Brook-street, aged 64.

SKIPWORTH.—On Dec. 17th, very suddenly, at Market Overton, Oakham, Philip Lyonel Grey Skipworth, M.R.C.S., L.R.C.P., aged 55.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

THE Guernsey and Alderney Division of the British Medical Association having learned of the further curtailment of the already inadequate scale of salaries for Poor-law Board appointments in the Channel Islands, is advising intending applicants to refer to the General Secretary of the Association at Tavistock-square.

Notes, Comments, and Abstracts.

THE HISTORY OF PUBLIC HEALTH LEGISLATION IN ENGLAND.

A Chadwick lecture on Legal Conceptions of Public Health was given by Mr. WILLIAM A. ROBSON, Ph.D., Barrister-at-Law, at the Royal Sanitary Institute on Dec. 13th.

Public health legislation, said Mr. Robson, had existed in England from comparatively early times, but was of a spasmodic character and dealt with isolated matters affecting health; in the reign of Richard II. for instance, it was enacted that the filth and entrails of slaughtered beasts should not be put into ditches under a penalty of £20; in 1576 an enactment prescribed a penalty for not scouring ditches by the roadside. Later, Lord Chief Justice Coke, commenting on an Act of James I., which made it a felony if a person with the plague "wilfully and contemptuously goes and converses in company," was apparently surprised to find that such an Act applied to person of all degrees. An early forerunner of the Sale of Food and Drugs Acts was an Act of Charles II., whereby French wine was not to be mixed with Spanish wine, cider, &c. After the Great Fire of 1666 statutes were made for the rebuilding of London with broad streets and for limiting the height of the houses. In 1753 legislation required ships to carry out quarantine more readily; in the event of refusal to proceed to the quarantine station the authorities were allowed to fire on the ships. These spasmodic attempts at sanitary legislation of a penal character were futile because there was no administrative authority to watch over it and carry it out; the Industrial Revolution bringing about the massing of large numbers of people in small urban areas made such gentle and self-reliant legislation ineffective. Broadly speaking, the suppression of nuisances comprised almost the whole system of public health for hundreds of years preceding the nineteenth century. The new idea of sanitation evolved by Chadwick had the celebrated lawyer, Toulmin Smith, as its great opponent; with incredible learning and care he proved that it was an infringement on the constitutional liberty of an Englishman to require him to keep himself clean. Health by Act of Parliament he declared to be impossible; the idea of setting up a separate Department of State to administer health legislation was against the Constitution; the enforcement of a sanitary code was on the same basis as the enforcement of a religious creed. In a classical work "The Parish," he stigmatised all this effort as communism. In 1848 the first general Act, dealing with public health from the modern point of view, was passed; it set up a General Board of Health and enabled certain provisions such as water-supply and sewers to be made. The whole of the structure of this legislation was cautious; for instance, a commission of inquiry was not to be sent to any provincial town unless the annual death-rate exceeded a certain figure. The Act of 1872 divided the country into sanitary districts, it permitted the appointment of medical officers of health and inspectors of nuisances, and established the principle of the grant-in-aid, which Mr. Robson classed with drains as among the greatest of English inventions. The existing Public Health Acts were codified in the Act of 1875. In the main the structure of the Public Health Acts have not changed, and a comparison of the Public Health Acts of 1925 and 1875 shows that both are concerned with the same elementary subjects, such as streets and cellar dwellings. The more important legislation on health matters is contained in other Acts such as the Sale of Food and Drugs Acts and the Milk and Dairies Act, 1922, which aim at ensuring a pure food-supply; the Factory Act of 1901, which deals with the health and safety of millions of employed persons; the Merchant Shipping Acts, dealing with the health of crews; the Maternity and Child Welfare Act of 1918, in which a new idea—the responsibility of the State for the health of the expectant and nursing mother and of young children under 5 years—finds its way to the Statute Book; the great Education Act of 1921, Part VII. of which deals entirely with the health of children; the Workmen's Compensation Act, a means of bringing indirect pressure to bear on employers to prevent occupational diseases; and the Housing Acts passed since the war. To-day public health, as such, is seldom thought of by the legislature; it is regarded as an important matter to be taken into account in dealing with a large number of other problems with which it is now seen to be closely connected.

With the development of preventive medicine, continued Mr. Robson, there has been a development of preventive justice which enables the courts to order the removal of dangers before they spread disease. To-day a diseased carcass can be condemned before it has set up disease, whereas in the legislation of Charles II. the French wine had to be already adulterated before a penalty could be enforced. Other outstanding features in the legal framework of the English Public Health system include (1) an autonomous local authority elected on a democratic basis, as contrasted with the French prefectoral system; (2) inspection, coördination, and advice from the Central Government made more acceptable than it might otherwise be by the ingenious device of the grant-in-aid; (3) powers in default by a local authority over a private citizen, by a county council over an inferior authority and finally by the Minister of Health; and (4) a great extension in the conception of what is involved in the public health idea. The whole question of noise, for instance, and its effect on health will eventually be considered a matter of first importance; beautiful surroundings in themselves may be found to be an element in the maintenance of health. Mr. Robson thought that an expert administration will not carry us far enough, and that the newer legislation will set up advisory bodies with powers to spend money. New factors in public health will arise, education in civics will bring about a state of affairs in which advances will not be the result of legal sanctions but of voluntary effort, and public opinion is the greatest sanction of all.

MEDICAL LITERATURE AND JOURNALISM.

IN a lecture at the Royal Institution on Thursday, Dec. 9th, Sir Squire Sprigge traced the development of medical literature from its origin in the Corpus Hippocraticum down to the present day. Disclaiming any attempt to review medical history, except in so far as it was represented by the great authors whose names were landmarks, he referred to the records of the famous anatomical work of the Alexandrian School in relation to the knowledge of structure displayed by Hippocrates, and indicated the additions made to scientific learning in their several ways by Galen and Celsus. In the Dark Ages, he said, no medical works of any significance appeared, the literary activity of those times being represented mainly by theological disputes; but when the story was taken up by the Arabian school of medicine—an outcome of the rise of the Mahometan faith—real advances occurred as was clear from the writings of Avicenna and others. When European learning revived with the Renaissance there were many authors, the lecturer said, to be mentioned both for their clinical contributions to the science and their anatomical researches preparatory to Harvey's great discovery. These he enumerated, with comments upon their individual discoveries, ending with an expression of regret at the destruction of Hunter's original work on comparative anatomy, which had perished in the absence of any medical journalism.

On Thursday, Dec. 16th, Sir Squire Sprigge dealt with medical journalism, and began by pointing out that the invention of printing was followed by no real developments in any journalism, as to-day understood, for many years, the place of the newspaper in the seventeenth century being taken by "News-Letters" and "Corantos" which had but a small circulation, and were the development of private communications to distinguished persons by agents who were called "intelligencers," and often were indistinguishable from political spies. In the middle of the seventeenth century letters of this sort began to be printed, mainly in Holland, but, said the lecturer, Governments, and especially the British Government and the Star Chamber, visited with severe penalties those who attempted to circulate the Dutch "News-Letters" in this country, or to print their similars in England. A few gazettes received a licence, the *London Gazette* remaining to-day as their only descendant. When in the next century journalism began to arrive, there were no papers devoted to science, and the early scientific or philosophic compendiums, while purporting to report medical affairs together with all other scientific or artistic matter, practically excluded medicine. At the close of the eighteenth century, and spurred by a continental model, medical journalism appeared in the form of certain monthly magazines, whose demand, said the lecturer, could be gauged by the fact that two of them soon took to quarterly issue; and it was not till 1823, when THE LANCET was founded by Thomas Wakley, the coroner for West London and Member of Parliament for Finsbury, that any weekly journal was in existence devoted solely to the publication of medical literature and the consideration of medical politics. The lecturer described the sensational episodes associated with Wakley's early attempts to reform medical education and hospital administration which gradually came to receive the support of the very persons who had been initially attacked, with the result that in 1858 the Medical Act was passed which secured the standardisation of medical education and the publication of a Government Register on which the public could find the names of the properly qualified. The lecturer concluded by contrasting the position of 100 years ago when there was only one weekly medical journal and that of to-day when the catalogue of any large library would show four or five columns devoted to the subject.

INTERNATIONAL AID FOR MERCHANT SEAMEN.

THE report of the International Red Cross Conference on the Health of Seamen held last summer in Oslo, Bergen, and Trondhjem has just appeared.[1] It contains important international data on the problems of the health and welfare of seamen. In addition to the proceedings of the Conference, in which delegates from most important maritime countries took part, as well as representatives of the League of Nations, International Labour Office, and the ship-owners' and seamen's organisations, there are reports from Canada, Finland, France, Germany, Great Britain, Holland, Italy, Norway, Spain, and the United States of America.

The Conference, it will be recalled, was convened by the Norwegian Red Cross Society and the League of Red Cross Societies to bring together the national Red Cross Societies of the maritime countries and other organisations interested in the seaman, in order to investigate measures for his welfare, and to examine what the Norwegian Red Cross Society had already done in this field. This Society had tentatively established medical stations for seamen in 21 medical ports, had published in Norwegian a medical manual for ships not carrying a doctor, and had prepared a standard medicine-chest, also intended for ships not carrying a doctor.

Bureaux in Sea-ports.

The resolutions passed by the Conference recommended inter alia the establishment of bureaux in seaports throughout the world for furthering the health and general welfare of seamen, their functions being to furnish (*a*) treatment or information as to where appropriate medical advice and treatment could be secured; (*b*) postal facilities; and (*c*) information as to the local recreational and social facilities and sleeping accommodation. It was further recommended that a standing committee on the welfare of seamen should be appointed by the League of Red Cross Societies in coöperation with the League of Nations, the International Labour Office, and other national and international organisations concerned. This committee was to investigate the standardisation of ships' medicine-chests, medical manuals, and a wireless code for medical consultations at sea. It was also to inquire into welfare conditions on board and in port, and the provision of recreational facilities for seamen of all nationalities.

All the speakers at the Oslo Conference emphasised the importance of international aid for merchant seamen. Every seaman spends a large part of his life in foreign ports, and it is just in such places, where, after the monotony of a long voyage, he lands to find himself a stranger, that he most needs help and guidance. Such help will only be forthcoming through international agreement and effort.

Dr. Ustvedt (Norway) pointed out the special dangers to which sailors are exposed, particularly tropical and venereal diseases. To both they frequently fall victim through ignorance, less frequently through apathy. The first step is to teach them the nature of these diseases and how to protect themselves against them. With regard to venereal disease, something must be done to raise the mental and moral outlook of the seaman and to give him some interests outside his work. Ships' libraries are a step in this direction, but there are not nearly enough of these.

Dr. Engelsen (Norway) put in a plea for Red Cross medical stations in ports and emphasised the support which the Norwegian Medical Association had given in this direction. Later on he spoke of the need for compulsory medical examination for all seamen prior to embarkation.

Free Treatment of Venereal Disease.

Prof. Bruusgaard (Norway) spoke of the importance of early treatment of syphilis, and instanced the results obtained in Sweden since the passing of the law of 1918 instituting free treatment for the general public. Between 1919 and 1924 the yearly number of cases of acquired syphilis fell from 3739 to 600 among men and from 2084 to 250 among women. The decrease for gonorrhœa was from 15,157 to 8020 for men and from 5314 to 2279 for women. In Denmark, where there is a law based on the same principle, a considerable decline has also been noted, but it is less striking than that in Sweden. In Belgium, where free treatment has been available for some years, the results show a decline of four-fifths. In Oslo during the same period the number of notified cases of infectious syphilis fell from 656 to 486 among men and from 258 to 214 among women, but the number of cases of gonorrhœa actually increased. Prof. Bruusgaard considered these figures too high and attributed them to defects in the Norwegian system. As to seamen, he advocated a methodically conducted educational campaign and easy access to free treatment, which should be carried out ashore.

Prof. Almkvist (Sweden) drew a sympathetic picture of the seaman's life and psychology and pointed out the combination of circumstances—extremely strong temptations, poor capacity to resist, and serious danger of infection—which often led to his downfall. He regretted the lack of statistics for the merchant service, but quoted comparative figures for the German, British, and American navies, and showed the rapid decrease of venereal diseases in the German navy after the introduction of prophylactic treatment in 1899. He also showed how unfavourably the venereal disease rate for the Swedish navy (15·5 per 1000 in 1924–25) compared with that for the general population in Sweden (1·88 per 1000 inhabitants in 1924). Prof. Almkvist recommended the cleansing of ports from all those who exploit seamen, the increase of recreational facilities, and he strongly advocated the provision of prophylactic treatment on board.

The danger of tuberculosis spreading on ships was mentioned by Dr. Heitmann (Norway), who pointed out how easy it was for a tuberculous seaman to embark on a long voyage without his disease being discovered. Dr. Clark (United States Public Health Service) reiterated the importance of prompt discovery of tuberculosis among seamen and outlined the American hospital system for tuberculous sailors.

Mr. Bowden (Great Britain) explained the National Health Insurance Scheme as it applied to seamen.

Legislation in Various Countries.

The second part of the report contains useful data regarding legislation in the various countries and other measures which have been taken for the health and welfare of seamen. Canada has a sick mariners' fund, to which all ships entering her ports contribute, and they thereby acquire the right to send sick members of their crew to hospital free of charge. Finland sends 24,125 of her sons to sea in Finnish vessels and 20,000 more in foreign vessels—a large number for a small country. The Finnish Sailors' Law of 1924 provides for compulsory medical examination and free treatment during sickness at the ship-owners' expense. Dr. Valtari (Finland) reported that, of Finnish sailors in hospital, 68 per cent. were suffering from venereal disease, 18 per cent. from affections of the lungs, 10 per cent. from accidents, and about 4 per cent. from insanity or weakmindedness. Germany has a *See-Berufs-Genossenschaft*, which undertakes seamen's insurance and looks after their welfare and protection against accidents. Great Britain has a law that ships carrying over 100 persons must carry a duly qualified medical man, but this touches only a minority; the total number of surgeons on 9744 vessels in 1923 was only 370. In Spanish ports seamen, of whatever nationality, receive free treatment in either Red Cross dispensaries or naval stations. The United States Public Health Service operates 25 marine hospitals and 127 other relief stations in the principal American ports.

Many other facts concerning merchant seamen and their welfare are contained in this section of the report.

ATAVISM, CHRISTMAS AND MR. PEPYS.

It is said that in bygone days the people of St. Kilda were sometimes overtaken by an unreasonable sense of terror. Losing their nerve and being filled with a strange dread, they would slink off to hide in caves in the middle of the island, and there would remain a day or two before returning sheepishly to their homes. The outside observer might think that the modern celebration of Christmas had some of the features of such an epidemic. Every year the population makes a premeditated attempt to escape from the bothers and terrors of its daily business. It rushes off to the privacy of its family circle and does its best to believe in primitive pleasures as proof against the cold realities of things outside.

The attainment of so simple a state of mind, as everyone knows, involves a lot of preparation; nothing must be lacking to make Christmas different from ordinary days. The presents, the cards, the food, the carols, the good wishes—these all form entrenchments behind which the harassed mind may imagine that simple things are best. Finally, the literature of Christmas should suit the food. At all costs the wrong books must be excluded from the ring so carefully prepared; introspection or the study of calories can have no part in a successful Christmas. Of the right books none better can be found than the edition of Samuel Pepys's Diary now prepared by Mr. O. F. Morshead under the name of "Everybody's Pepys" (G. Bell and Sons, London, 1926, pp. 570, price 10*s*. 6*d*.). The Diary has all the pleasant simplicity that belongs to the season; it restores a sense of proportion (often badly needed) by its description of another age; its people are fully up to date though their problems have a suitable tinge of antiquity. Their servants, for instance, were as troublesome as ours, as may be seen from this extract from the admirable index:—

Doll, chambermaid, very ugly; leaves. *Sarah*, combs Pepys's hair; Pepys and Mrs. Pepys fall out about her;

leaves; goes to Sir W. Pen; he puts her away. *Mary*, housemaid, left after ten weeks. *Susan*, cookmaid, a willing wench but no good cook; Pepys gives her sixpence for doing well (became distracted and drunk and departed). *Hannah*, cookmaid (left in a huff). *Jinny*, being cleansed of lice by Mrs. Pepys, runs away; "no luck in maids nowadays."

All this may strike a chord of sympathy in the modern householder, but since no longer do we baste our maids with a broom—whilst they no longer sit by the bedside mending our breeches, or rise at 2 in the morning to do the washing—it is so remote that it gives more pleasure than pain. The troubles of our neighbours, even after centuries, are often very soothing.

The present edition reduces a book of over a million words to one of reasonable proportions. There is no annoying bowdlerisation, and the charm of the original remains. No volume containing so many illustrations by Mr. Ernest H. Shepard could fail to attract the public, but this one would recommend itself without them. When after Christmas the reader returns, somewhat sheepishly, to real life, it will remain to recall, perhaps, a season of atavistic enjoyment.

PUBLIC HEALTH IN SOMALILAND.

THIS British Protectorate, proclaimed in 1884, contains about 68,000 square miles, and has an estimated population of 300,000, mostly Mohammedans. A new hospital, opened in June, 1925, contains two large wards, each of 28 beds, and three private wards. In addition, there is a ward of 40 beds for paupers and aged people who need medical treatment other than hospital treatment. There is an excellent operating theatre, an X ray department, and a research laboratory furnished with the most up-to-date equipment. The figures relating to the number of admissions to hospital and attendance of out-patients show an increase, which indicates a growing confidence on the part of the native population in the efficiency of European methods as opposed to their own primitive ways. The following is a schedule of the cases treated in 1925: scurvy 6, tropical ulcers 4469, beri-beri 2, constipation 3500, malaria 830, relapsing fever 118, leishmaniasis 1 (the first known case in Somaliland), erysipelas 1, chicken-pox 62, influenza 247, dengue 85, dysentery 30, diarrhœa 379, tuberculosis 278, leprosy 6, measles 8, syphilis 601, gonorrhœa 263. It is stated that during the year the general health of the European population was good; 6 Europeans contracted dengue in Berbera.

WOODHALL SPA.

THIS Lincolnshire spring, which was discovered a little over 100 years ago in the course of an unsatisfactory boring for coal, provides at a depth of 500 feet a strongly saline water containing unusual quantities of bromine, iodine, and calcium, which has been found serviceable in the treatment of neurasthenia, myxœdema, and enlarged glands. The water is applied externally to cases of rheumatism, fibrositis, surgical thickenings, and fibrous ankyloses in the neighbourhood of joints, as well as of subinvolution and pelvic inflammations. The natural deposit in the spring is employed in mud baths or "fango" packs. At the bath establishment there is a trained nursing and massage staff, competent to give various forms of electrical treatment—baths, ionisation, Bergonié, reducing—combined with radiant heat or ultra-violet light, and the various baths (Nauheim, Bertholet, local steam, vapour) and douches. Ultra-violet light has been applied to cases of psoriasis and other cutaneous disorders, and to children convalescing from infectious disease. The establishment is situated among fine trees in a charming wood, the good roads, which dry quickly after rain owing to the gravelly subsoil, encourage gentle walking exercise; there are many seats, and little motor traffic to disturb. Woodhall is in the midst of an agricultural district, Food is fresh, and as for fish, Grimsby is but 30 miles away. The golf links are close to the Spa. A through-carriage runs to and from King's Cross daily in 3½ hours. The Spa has no physician-superintendent, but two physicians are attached to the Alexandra Hospital, which has 30 beds for patients of either sex suffering from rheumatic conditions likely to benefit by local treatment. A home for gentlewomen provides at moderate rates for 20 ladies similarly affected.

ENERGEN BREAD.

WE are asked by the proprietors of Energen Bread, Energen Foods Co., Ltd., Willesden, to call attention to the fact that the company are supplying to diabetics and other patients in poor circumstances Energen bread at a discount of 15 per cent. In order to secure the discount, the dealer who supplies the bread must receive from a doctor a certificate showing that the patient is indigent.

STANDARD DRESSINGS.

THE Minister of Health has suggested to boards of guardians in England and Wales the desirability of securing uniform good quality in the surgical dressings used in the hospitals under their charge. For National Health Insurance purposes dressings must conform to standards specified in the British Pharmaceutical Codex, the testing of samples being carried out at the Manchester Testing House, the director of which is prepared to test and report, at specially reduced fees, upon samples sent by boards of guardians.

The more important surgical dressings for which the British Pharmaceutical Codex specifications are available are as follows:—

Bandages:—Calico (bleached and unbleached); crêpe; open wove (white and grey); and plaster-of-Paris.

Gauzes:—Boric; carbolic; double cyanide; iodoform; picric; sal-alembroth; sublimate; and unmedicated.

Cotton Wools, absorbent:—Boric; sal-alembroth; and unmedicated.

Gauze and Cotton Tissue. Lints:—Boric; sal-alembroth; and unmedicated.

Tows:—Carbolised and unmedicated.

The testing house holds a sample of unmedicated cotton wool which complies with the specification of the British Pharmaceutical Codex. The Minister points out the economy secured by the Health Insurance service from the adoption of a standard length of four yards to replace the usual six yards standard for bandages.

TREATMENT OF TAPEWORM.

Dr. B. Klein,[1] assistant in Prof. W. Mollow's clinic at the University of Sofia, thinks that granati cortex has lately been too little used in the treatment of tapeworm. He attributes its disrepute to the fact that it has been given by the mouth, whereas he finds it far better to pass it into the duodenum by Einhorn's catheter. He infuses 150 g. of the powdered root bark for 12 hours in a litre of water, and boils down the infusion to one half. Before use this preparation is warmed to 100° F., and three doses—each of 65 c.cm.—are given at half-hour intervals; they are followed by a laxative, after which the catheter is carefully withdrawn. Since March, 1923, he has treated 19 cases, and has had only two failures; in these cases too sudden withdrawal of the catheter caused vomiting. The other 17 comprised 12 cases of *Tænia mediocanellata*, four of *T. solium*, and one of *Hymenolepis nana*. Twelve of the tæniæ were expelled complete; four were broken, but their heads were recovered with the segments. The *H. nana* was not found, but no ova have been seen in the two years since the treatment was given. Dr. Klein states that this method was employed by V. Bettleheim in 1887, and that in 1924 H. Schneider had great success from a combined treatment with granati cortex and filix mas.

BOURNVILLE PRODUCTS.

WE have received from Messrs. Cadbury Brothers assorted specimens of the latest productions from Bournville. These include boxes of Carnival, King George, and Marlborough chocolates, which are established favourites with different tastes, and boxes of assorted tablets flavoured with fruit or nuts, and in one case definitely compounded to appeal under the title of "Bitter" to those whose palates do not allow them to relish anything sweet. It is superfluous to mention the qualities of Bournville Cocoa as a beverage made with water, milk and water, or milk, and sweetened according to will. All the samples are put up with the attention to appearance associated with the firm.

CHROMIUM-COATED INSTRUMENTS.

Messrs. J. Smith, Northampton Plating Works, 230 St. John-street, Clerkenwell, London, E.C., have submitted to us a nickel-silver tongue depressor and a vaccinator of steel, both of which have been subjected to a deposit of chromium. The claim made for them is that they do not tarnish, corrode, or rust when in use, and tests would seem to substantiate this claim. Placed for 24 hours in strong "Fecto" (Parke Davis) solution, 1–20 perchloride of mercury or 1–20 carbolic, the instruments do not show corrosion neither does several days' submersion in water appear to affect them. If the chromium deposit stands the test of time, instruments treated in this way should be welcomed by the surgeon.

ÆTHER PURISS.

Æther Puriss, the product of the British Drug Houses Ltd., and noticed in THE LANCET of May 23rd, 1925 (p. 1083), is now being sold at a price comparable with that of ordinary anæsthetic ether. The reduction has been made possible by an increased demand for this pure ethyl ether.

[1] Arch. f. Schiffs- u. Tropen-Hygiene, 30, iii., 250.

INDEX TO VOLUME II., 1926.

☞ *Readers in search of a given subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral, Heart and Cardiac, Liver and Hepatic, Child and Infant, Goitre and Thyroid, Diabetes, Glycosuria and Sugar, Eye, Ophthalmic, and Vision, Lunacy and Mental Disease, Arsenobenzol and Salvarsan, &c., &c., and that regional headings are more frequently used than pathological. Institutions and Corporations with the right to the prefix Royal will be found under that prefix, with the exception of Hospitals, which will be found under that heading; and Medical Societies, which are separately indexed under Societies. All Universities are indexed under the word University. (A.) = Annotation, (C.) = Correspondence, (N.I.) = New Inventions, (L.A.) = Leading Article, (M.L.) = Medico-legal, (M.T.T.) = Modern Technique in Treatment, (O.) = Obituary, (P.I.) = Parliamentary Intelligence, (R.) = Review, and (R. and A.R.) = Reports and Analytical Records.*

A Concordance of page numbers and dates of Issue will be found at the end of the Index.

JUST ISSUED Stevens' Practice of Medicine. *SECOND EDITION*

Dr. Stevens' Practice of Medicine is a personal work because the methods detailed are those which Dr. Stevens has himself found to give the desired results in actual practice. Every clinical diagnostic test is carefully given and the numerous diagnostic tables offer an invaluable help in determining by elimination the nature of the disease. More attention is given to the treatment of disease than in any other work of similar size. In most cases, one definite plan of treatment is given, and that the one which Dr. Stevens has found successful. Naturally, reference to the work of other authorities is made, but the book is essentially a summary of Dr. Stevens' thirty-two years of hospital and private practice. For the new edition the work has undergone a most thorough revision.

"A volume which will take a worthy place amongst the accepted text-books of medicine."—THE LANCET.

By A. A. STEVENS, M.D., Professor of Applied Therapeutics, University of Pennsylvania. Octavo of 1,174 pages illustrated. Cloth, 35s. net.

THE LIBRARY OF THE UNIVERSITY OF ILLINOIS

DROITWICH, THE BRINE BATHS SPA

PRACTICALLY IN THE CENTRE OF ENGLAND with excellent railway services, and only 2½ hours from Paddington, makes a direct appeal to invalids. Situate in a charming district and possessing the strongest known saline waters, it may be said to be unique, and is attracting the attention of medical men far and near.

The baths are especially valuable for the rheumatic group of diseases, and are all given in the Natural Brine pumped direct from the Springs. Reclining Baths, Douche, Aix Douche, Needle, Vapour, Aeration Baths, and Nauheim treatment; also three magnificent Brine Swimming Baths.

Illustrated Booklet of the Spa from Baths Manager:—BERKELEY HOLLYER, 3, Baths Offices, Droitwich.

VALENTINE'S MEAT-JUICE

In **Hospital** and **Private Practice** and **in their own persons** when ill, **Physicians** have **demonstrated** the **power** of **Valentine's Meat-Juice** to **Sustain** and **Strengthen** the weakened **Vital Forces** when the **Digestive Organs** are **Impaired.**

Debility, Exhaustion and Anaemia.

Dr. Julian Calleja, *Pres. Royal Academy of Medicine, Madrid, Spain:* "It is with the greatest pleasure that I inform you that I consider VALENTINE'S PREPARATION OF MEAT-JUICE to be of a very superior order for invigorating the nervous system, for which I use it myself, and prescribe it to my patients."

Ross H. Skillern, M. D., *Laryngologist Rush Hospital for Consumption, Philadelphia, Pa.:* "I, myself, had the misfortune to be seized with an attack of Cerebro Spinal Meningitis and after a critical illness recovered. My mainstay during the attack was VALENTINE'S MEAT-JUICE, and I can assure it materially aided in my recovery."

For Sale by European and American Chemists and Druggists.

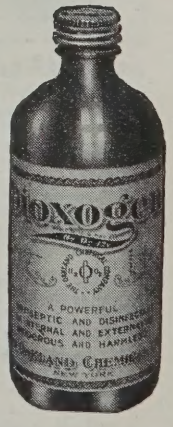
Wound Treatment with Dioxogen

(Trade H_2O_2 12v Mark)

"Dioxogen" is most effective for treating wounds because it combines high germicidal potency with absolute safety in use. "Dioxogen" used on fresh wounds stops capillary bleeding, prevents suppuration and promotes cicatrization; where infection is a complication it destroys the invading organisms and their toxins, loosens foreign matter, and exerts a general cleansing and antiseptic action. The action of "Dioxogen" depends on the relatively large volume of pure nascent oxygen liberated on contact with the blood and other body fluids. It is distinguished from ordinary hydrogen peroxide by its exceptional purity, strength, (20% higher than B.P. standard) and remarkable keeping qualities.



In 4 oz., 8 oz. and 16 oz. bottles.

Descriptive booklet and clinical trial sample on application to

Allen & Hanburys Ltd., 37 Lombard St., E.C.3.

THIS PREPARATION IS NOW OBTAINABLE IN 5-oz. BOTTLES.

MIST. HEPATICA CONC. (HEWLETT'S)

COMPOSITION.—Ext. Cascaræ, Ext. Rhei, Jalapin, Podophyllin, Cocainæ Hydrochlor., 1-20th gr. in each fluid drachm.

This preparation does not come under the Dangerous Drugs Act.

THIS excellent compound, first introduced as a general **aperient** and **cholagogue,** has now become a popular remedy in that class of cases spoken of as Chronic Biliousness, in Catarrhal Jaundice, and in the Jaundice of simple Hepatic Torpor. **In passive or habitual Congestion of the Liver, so frequently met with, it has been used with marked benefit.**

In the treatment of acute or temporary constipation, frequently met with in the convalescence from acute disease and in pregnancy, or in the constipation due to sedentary habits, to a deficiency of intestinal secretion and of peristalsis the mixture can be prescribed with wonderful effect.

The Dose is from 10 to 60 minims, according to the age and condition of the patient. One drachm is a direct aperient and is not accompanied by griping or tenesmus.

Packed for Dispensing only in 5-oz., 10-oz., 22-oz., 40-oz., and 90-oz. Bottles.

Price in England, 12/6 per lb.

Please write: "Mist. Hepatica Conc. (HEWLETT'S)" to ensure obtaining this Preparation.

This preparation is also supplied "sine Cocaina," the dose and price remaining the same.

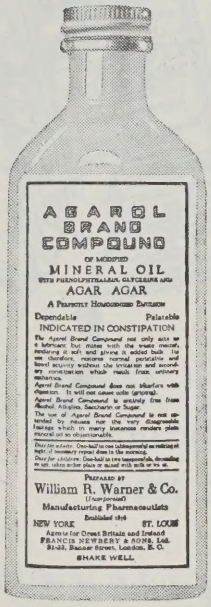
More than a Laxative



AGAROL is the *original* Mineral Oil—Agar-Agar Emulsion, and has these special advantages:

Perfectly homogenized and stable; pleasant taste without artificial flavouring; freedom from sugar, alkalies and alcohol; no contraindications; no oil leakage; no griping or pain; no nausea or gastric disturbances; not habit forming.

¶ *A generous supply for clinically testing will be sent to physicians on request.*

AMONG the newer remedies of proven worth there is hardly one that has won the favour and esteem of thorough-going, conservative medical men more surely and completely than

AGAROL
BRAND
COMPOUND

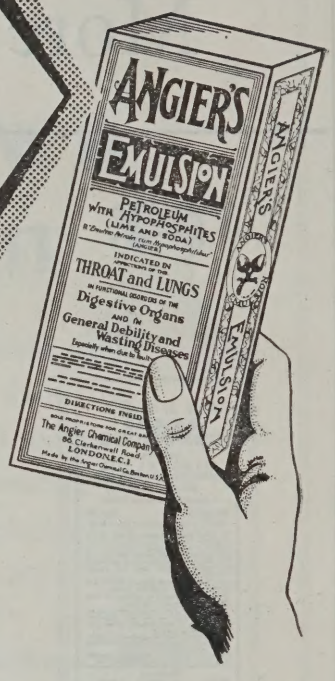
This is due to the physiological manner of its action and the remarkable dependability of its effects.

A brief consideration of the composition of Agarol—with its carefully balanced proportions of pure mineral oil, agar-agar and phenolphthalein — followed by a practical clinical test, will convince the most critical practitioner that here is no ordinary laxative that produces merely a single evacuation and then leaves the bowels more constipated than before, but a rational corrective that he can rely upon to give him the aid he seeks in restoring the physiological regularity of the bowels.

Francis Newbery & Sons, Ltd., 31-33 Banner Street, London, E.C.1

Prepared by WILLIAM R. WARNER & CO., INC., *Manufacturing Pharmacists Since* 1856

In Convalescence
after Influenza, Pleurisy, Pneumonia, Bronchitis.



The soothing, inflammation-allaying properties of Angier's Emulsion and its general tonic effects especially commend its use in convalescence from acute respiratory affections. It will clear up any remaining catarrh, whether of the respiratory or digestive organs. It will restore tone to the digestive functions, and greatly improve assimilation and nutrition.

An absolutely perfect emulsion, it is presented in a form pleasing to the taste and acceptable to the most fastidious. Moreover, it can be administered in conjunction with other remedies, and will be found a perfect vehicle for salol, aspirin, bismuth, &c.

Angier's Emulsion is made with petroleum specially purified for internal use. It is the original petroleum emulsion—the result of many years of careful research and experiment.

BENGER'S
FOOD
(REGISTERED TRADE MARK.)
For Infants, Invalids, and the Aged.
Manufacturers & Sole Proprietors: BENGER'S FOOD Ltd.
MANCHESTER, ENGLAND.
KEEP IN A COOL DRY PLACE.

Benger's Food—*the adjustable diet.*

The "LANCET" describes it as "Mr. Benger's admirable preparation."

Owing to the presence of the natural enzymes of digestion (*Amylopsin* and *Trypsin*), and its method of preparation for a patient, the extent of self-digestion of Benger's Food and the milk with which it is mixed *can be regulated to suit the digestive powers of the patient.*

Benger's Food is prepared with fresh cows' milk. It forms a dainty cream which becomes the easier of digestion the longer it is allowed to stand after mixing. The process may be arrested at any time by simply bringing the mixture to the boil. (A useful average time for standing is 15 minutes).

Patients ordinarily unable to digest milk can take this mixture satisfactorily, as the Benger's food so softens the casein that when under the influence of the gastric juice it forms into minute flocculi instead of a heavy curd.

Benger's Food is of the highest nutrient value and is not found to pall, even when taken over long periods.

A Physician's Sample will be sent post free to any member of the Medical Profession making application to the Proprietors—

BENGER'S FOOD, LTD., Otter Works, MANCHESTER.

For the Delicate Child

THE delicate, backward, nervous or unstable child is ever a problem in the children's clinic. Very frequently faulty metabolism lies at the seat of the trouble, involving an inherent incapacity to make adequate use of the essential and vitalizing elements of ordinary nourishment.

Liberality of the nitrogenous or building elements of the diet to the limit of digestive capacity is recommended by authority. Two teaspoonfuls of "Ovaltine" dissolved in half a pint of milk produces a tonic and nutritive beverage well adapted to this requirement. It gives a protein to non-protein ratio of approximately 1 to 3.5 which is a liberal apportionment of the nitrogenous element. The proteins of "Ovaltine" are those derived from "Winter" Malted Barley, Eggs and Milk, valued sources of nutritive material for the delicate child.

OVALTINE
TONIC FOOD BEVERAGE

Such a diet taxes to the minimum the digestive function because "Ovaltine" modifies the milk curd to a light, easily digested coagulum. Moreover, clinical evidence plainly shows that "Ovaltine" is well borne in spite of food intolerance, anorexia and those numerous perversities of alimentation which undermine the constitution and frequently result in permanent injury.

A liberal supply sent free for clinical trial on request

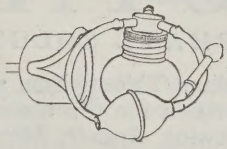
M215

The Effective Treatment of Tonsillitis, Sore Throat and colds in general

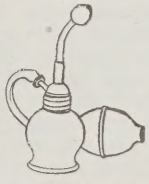
NEBOLINE COMPOUND No. 2

Contains the oils of Scotch Pine, Eucalyptus and Cassia with Camphor, Menthol and Eucaine Hydrochloride (3¾ grains to 1 fl. oz) in a Benzoin basis.

This is one of the 'Neboline' Compounds specially prepared for use in the 'Universal Vaporiser' and the 'Aeriser' described below. In this compound the prolonged effect of eucaine is secured without the usual reaction, a quality which largely accounts for the increasing use of "No. 2."



The 'Vaporiser' reduces aqueous, oily and balsamic solutions to an almost invisible vapour without the use of steam or heat, and carries them in actual substance to the most remote positions of the respiratory tract and middle ear, not excepting the air cells and nasal sinuses. The 'Aeriser' is a less expensive model. The **Lancet** says: "They render fluids like smoke."



The formulæ of the 'Neboline' Compounds is included in our brochure, "The Treatment of Pulmonary and Bronchial Affections," which will be posted free on request.

OBJECTS UPON WHICH ARE DEPICTED CERTAIN ROMAN DEITIES OF HEALING: (1) MEDAL WITH A FIGURE OF JUNO LUCINA; (2) PORTION OF AN ALTAR ORNAMENTED WITH A REPRESENTATION OF ÆSCULAPIUS; (3) MEDICINE SHOVEL DECORATED WITH THE HEAL OF MINERVA MEDICA.—Among the gods indigenous to the Romans, there were, originally, none who were specifically medical divinities. The function of healing was one of many evil-averting powers exercised by any one of the principal deities—Mars, Janus, Jupiter, Juno, Diana, Carna (or Carnea, a goddess of the underworld, the protectress of the physical well-being of man), and others. There was, in these early times, no such thing as rational medicine in Italy; "remedies" were purely magical in nature. Febris, a primitive Italian deity, "the averter of fever," was, however, specifically connected with healing; her name indicates that fever was as prevalent in the region about Rome in earliest times as at present. Certain deities later evolved specifically medical attributes, and a qualifying term was then added to their names to express this definite department of their functions: thus, Juno, as Lucina (or Sospita, Fluonia, Conservatrix, Dea Natio, Opigena, Kupra), became the goddess of childbirth and of woman's life. Juno Lucina was represented, as in the illustration here reproduced, accompanied by children. Minerva, as Minerva Medica or Minerva Memor, became the patroness of physicians; she healed, especially, diseases of the ear in her sanctuary near Placentia and prescribed medicines which were dispensed in her aboratory. Early in the third century B.C. the great divinity Asklepios was imported from Greece. As Æsculapius he throve so well that in course of time his cult, so clearly defined and recognised, partially absorbed or supplanted those of some among the indigenous gods. The Æsculapius here depicted as a Roman officer is a local form found in Syria and is reminiscent of Roman Empire building in the East and of the known devotion of soldiers in camp and veterans to the cult of Æsculapius.

DATE: From earliest times onward. The objects belong to the period of the Roman Empire.

INFANT DIET MATERIALS

MEAD'S

To approximate Breast Milk

COWS' MILK SHOULD BE RECONSTRUCTED

NOT ONLY

QUANTITATIVELY

by which is meant the modification of cows' milk so that it will contain approximately the same percentages of fat, salts, proteins, and carbohydrate as breast milk,

BUT ALSO

QUALITATIVELY

1.—Because the fat of cows' milk contains ten times more volatile fatty acids than the fat of breast milk.

2.—Because the protein of cows' milk contains four times more casein than lactalbumin, while the protein of breast milk contains more lactalbumin than casein.

3.—Because cows' milk contains three times more calcium salts than potassium salts, while breast milk contains more potassium salts than calcium salts.

RECOLAC

Reconstructed Milk

In RECOLAC these important differences, which are often disturbing factors in infant feeding, have all been corrected, and as a result, Recolac is pronounced "The form of Artificial Feeding which gives good results in a larger percentage of cases than any other."

INFANT MEADS MATERIALS

The Mead Policy.

There are no feeding directions on the tins of Mead's Recolac, thus leaving the feeding strictly under professional supervision. Literature supplied only to Doctors, Hospitals and Clinics.

Large Samples and a pocket chart showing usual feedings of Recolac will be sent on receipt of a post card.

THE MOST ACTIVE URIC ACID ELIMINANT

ATOQUINOL

(Allyl Phenylcinchoninester)

Atoquinol possesses pronounced analgesic, antipyretic and antiphlogistic properties. It has proved of great value when exhibited in the treatment of arthritis, gout (gastric, intestinal), neuralgia, sciatica, polyneuritis, rheumatism, etc., and it may with advantage replace the salicylates in many cases. Atoquinol is administered orally in the form of tablets (4 gr.), while Atoquinol Ointment, which is readily absorbed by the skin, may be applied locally in painful arthritis.

Trade **BYNOL** Marks

"A Perfect Combination of Malt Extract with Cod-Liver Oil"—*B.M.J.*

"Bynol" contains 30% by volume of the highest grade Norwegian Cod-Liver Oil very finely emulsified with the "Allenburys" Malt Extract and aromatics, thus producing a rich, easily digestible and palatable product. The main ingredients, particularly the Cod-Liver Oil, are rich in vitamins which are conserved in their full potency by the special processes used in the manufacture of the product. "Bynol" is of special value to those who require additional fat and vitamins beyond what is supplied by an ordinary dietary—to backward and weakly children, nursing mothers, and those suffering from malnutrition or having a predisposition to phthisis and respiratory diseases in general. The usual dosage is from one teaspoonful to one tablespoonful three times a day after meals.

In wide-mouthed jars containing 10 oz. 2/3; 20 oz. 4/-; 50 oz. 7/6.

Clinical trial sample will be sent post free to members of the Medical Profession.

MODERN METHODS OF TREATMENT OF

RHEUMATOID ARTHRITIS

The Laboratories, 245, Knightsbridge, S.W.7

Telephone: Sloane 3622

A COMPLETE investigation of the source or sources of infection in cases of *Rheumatoid Arthritis* is carried out and preparations of Autogenous vaccines supplied to medical practitioners *only* for the inclusive sum of £10 10 0.

N.B.—No treatment of Patients undertaken

The investigation comprises:—

1. Examination of nose and throat, cultures being taken.
2. Bacteriological, Microscopic and Chemical examination of urine.
3. Bacteriological examination of stools for abnormal organisms.
4. In female patients, Bacteriological examination of vaginal and uterine discharges, if any.
5. Wassermann reaction if indicated.
6. X Ray examination of teeth if indicated.
7. Preparation and supply of 20 cc. of autogenous vaccine in ampoules or bottle.
8. A full and complete report of the above investigations to medical attendant within from seven to ten days.

Medical men are invited to accompany their patients and see for themselves the methods of investigation. The Laboratory is open to inspection and the progress of the cultures can be observed from time to time.

When necessary arrangements can be made with the Medical Attendant for conducting the examination and taking the cultures at the patient's home, an extra charge being made of 5/- per mile.

A skilled and trained lady (late Matron of a General Hospital) is always in attendance.

Directors:—M. J. ROWLANDS, M.D.(Brux.), M.R.C.S.

These preparations consist solely of the essential rich juices of the finest British meats without the addition of water or any other substance. Entirely pure and highly nutritious and beneficial.

British made and prepared at the dietetic laboratories of Brand & Co., Ltd., London, S.W.8.

37 ROYAL APPOINTMENTS HELD CONTINUOUSLY SINCE GEORGE IV

"... of advantage to invalids"

Simonds Milk Stout has helped thousands of patients. You can recommend it, too.

While it has been proved conclusively that Stout contains more nutritive matter than the great majority of beverages, Simonds Milk Stout constitutes an *additionally* nutritious stimulant by reason of its specially-added milk-sugar ingredient. It is brewed in the old original manner from Malt and Hops, and contains only the natural alcohol supplied by the former. Besides its ordinary carbo-hydrate contents, the addition of 2·5 per cent of lactose, increases its real usefulness as an exceptionally pleasant tonic-beverage and permits of its special recommendation in cases where ordinary stouts would be unsuitable. Simonds Milk Stout is prepared and bottled with the utmost care always and is guaranteed pure.

Order also from the Leading Stores, including all Branches of the Victoria Wine Co. Ltd.

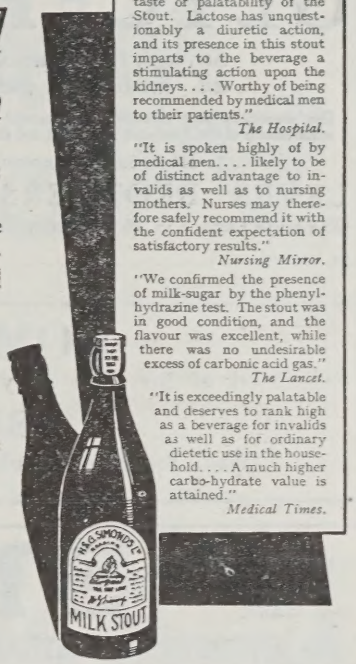
Medical Press Opinions.

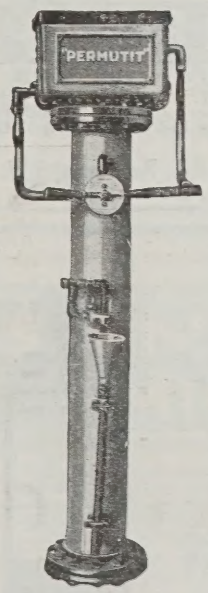
"The addition of the lactose has not in any way altered the taste or palatability of the Stout. Lactose has unquestionably a diuretic action, and its presence in this stout imparts to the beverage a stimulating action upon the kidneys. . . . Worthy of being recommended by medical men to their patients."
The Hospital.

"It is spoken highly of by medical men. . . . likely to be of distinct advantage to invalids as well as to nursing mothers. Nurses may therefore safely recommend it with the confident expectation of satisfactory results."
Nursing Mirror.

"We confirmed the presence of milk-sugar by the phenylhydrazine test. The stout was in good condition, and the flavour was excellent, while there was no undesirable excess of carbonic acid gas."
The Lancet.

"It is exceedingly palatable and deserves to rank high as a beverage for invalids as well as for ordinary dietetic use in the household. . . . A much higher carbo-hydrate value is attained."
Medical Times.





"Fits on the main.
Gives water like rain."

The Luxury and Convenience of Soft Water

FOR INTERNAL TREATMENT OF GONORRHŒA, URETHRITIS AND OTHER AFFECTIONS OF THE GENITO-URINARY TRACT.

Santal Midy Capsules
have been prescribed with uniform success for over 30 years. Distilled from carefully selected Mysore Sandal Wood, the oil is bland and remarkably

FREE FROM THE IRRITANT AND NAUSEATING EFFECTS
which are provoked by many preparations.

SANTAL MIDY

There is a marked absence of Gastric and other disturbances, diarrhœa and skin eruptions. Its mild chemotactic properties permit its administration in relatively large doses without fear of too violent reaction or intolerance.

SANTAL MIDY CAPSULES
may be prescribed and relied upon in all stages of Gonorrhœa and in other forms of Urethritis and affections of the Genito-urinary Tract. The capsules contain 5 drops, and usually 10 to 12 are given daily in divided doses.

Prepared in the Laboratoire de Pharmacologie Générale, 8, Rue Vivienne, Paris, and sold by most Chemists and wholesale Druggists throughout the world.
U.K. Agents: WILCOX, JOZEAU & CO., 15, Gt. St. Andrew St., W.C.2.

Infant Feeding

When it is decided to abandon breast feeding, the child is frequently in a weakened state. The change must involve the least possible trouble. Hence the new diet must be easily adaptable to correspond to whatever changes may arise. It is largely for this reason that doctors usually advise the adoption of Cow & Gate Milk Food in difficult cases.

Cow & Gate Milk Food

They know from clinical experience that the progress secured is identical to that resulting from breast milk.

The slightest risk of contamination at any stage, whether through delay or exposure, must be avoided. Cow & Gate Milk Food, being made in the West Country, and packed and despatched at once, removes any chance of harm even in the warmest weather. Try Cow & Gate Milk Food (Full Cream or Half Cream strengths) in your next case, and you will observe contentment and steady development from the first day.

Metropolitan Borough of Greenwich.

TO OBSTETRIC CONSULTANTS.

The Council of the Metropolitan Borough of Greenwich is prepared to receive offers from recognised Obstetric Consultants, who would be willing to have their names placed on a panel of some two or three members for service when a second medical opinion is required in connection with the treatment of cases of Puerperal Fever and Puerperal Pyrexia occurring in the Borough.

The fee offered by the Council for such services is £3 3s. per consultation, with the addition of £1 1s. for travelling expenses if advice only is needed, and where treatment is carried out a total fee of £5 5s. will be paid.

Communications in respect of the above should be forwarded to the Medical Officer of Health, The Borough Hall, Royal Hill, Greenwich, S.E. 10, from whom any further information may be obtained, and definite applications to be placed on such panel must be received by him not later than Wednesday, the 5th January, 1927.

FREDERICK J. SIMPSON, Town Clerk.

Town Hall, Greenwich-road, S.E. 10,
8th December, 1926.

West London Hospital, Hammersmith, W. 6.

(226 Beds.)—There is a vacancy for appointment as HONORARY SURGEON to the Throat, Nose and Ear Department, for which the present Assistant Surgeon to that Department is a candidate. In the event of his election there will be a vacancy for an Honorary Assistant Surgeon, Throat, Nose and Ear Department, for which post applications are also now invited.

Candidates must be Fellows of one of the Royal Colleges of Surgeons of England, Edinburgh, or Ireland, and must not be engaged in general practice. The successful candidate must be willing, in addition to his other duties, to undertake such teaching for the Post-Graduate College as the Board may approve, and periodically to deliver courses of lectures to Nurses.

Applications, with copies only of testimonials, should reach me not later than Saturday, 15th January. Candidates must attend the Medical Council meeting on Friday, 21st January, at 4.30 P.M., and prior to that date call upon and send copies of application and testimonials to each member thereof. They must not canvass members of the Board, but nevertheless must send copies of application and testimonials to each member thereof, and be in attendance at the Board Meeting on Tuesday, 25th January, at 5 P.M., when the election will be made.

H. A. MADGE, Secretary.

West London Hospital, Hammersmith-road, W. 6.

(226 Beds.) — Applications are invited for the post of HONORARY OBSTETRIC REGISTRAR for a period of one year, eligible for re-election annually. The duties include the preparation of the Obstetric Registrar's Report for the year and the supervision of the records of cases. The candidate appointed must be available as substitute for the Surgeon and Assistant Surgeon for Diseases of Women, and for emergency operations when required, and be prepared to undertake such teaching for the Post-Graduate College as the Board may approve.

Candidates are required to be registered under the Medical Act; to send applications so as to reach me not later than Saturday, 15th January next; to attend the Medical Council Meeting on Friday, 21st January, at 4.30 P.M., and prior to that date to call upon and send copies of application and testimonials to each member thereof; to abstain from canvassing, but nevertheless to send copies of application and testimonials to each member of the Board of Management, at whose meeting on Tuesday, 25th January, at 5 P.M. candidates must be in attendance.

H A. MADGE, Secretary.

THE SECRETARY,
The Medical Staff Committee, Bedford County Hospital.
December 13th, 1926.

Royal Devon and Exeter Hospital,

Exeter. (200 Beds.)

SENIOR HOUSE SURGEON.

Applications are invited for the post of Senior House Surgeon (Male) which will become vacant at this Hospital on January 6th, 1927. The appointment is for twelve months, but candidates are eligible for re-election.

Salary at the rate of £210 per annum, with board, apartments, and washing.

Applications, giving full particulars as to age and qualifications, together with certificate of registration and copies of three recent testimonials, should be sent to the undersigned on or before Friday next, 31st inst.

By order of the Committee.
December 20th, 1926. S. S. COLE, Secretary.

County Borough of Oldham.

PUBLIC HEALTH DEPARTMENT.

ASSISTANT MEDICAL OFFICER AND ASSISTANT TUBERCULOSIS OFFICER.

Applications from qualified Medical Men are invited for the position of Assistant Medical Officer of Health and Assistant Tuberculosis Officer.

Applicants must have special experience in Tuberculosis work. The Officer appointed will be required to reside within the Borough.

Salary £750 per annum.

Applications upon forms to be obtained from the Medical Officer of Health, Town Hall, Oldham, must be returned to him, accompanied by not more than three recent testimonials, not later than January 1st, 1927.

Canvassing in any form will disqualify.

JAMES B. WILKINSON, Medical Officer of Health.
Health Offices, Town Hall, Oldham.

Corporation of Calcutta.

Applications are invited for the post of the HEALTH OFFICER of Calcutta. The selected candidate must devote his whole time and attention to the duties of his office and will not be allowed to take up any outside work. He must be legally qualified for the practice of Medicine, Surgery, Midwifery, and must also be registered in the Medical Register as the holder of a Degree or Diploma in Sanitary Science, Public Health or State Medicine, under Section 21 of the Medical Act of 1886, or must possess a Diploma in Public Health of any Indian University. He must also possess at least ten years' practical experience as a Sanitarian or as M.O.H. of a city containing a population of at least 100,000 and should be able to administer the various departments employed on the sanitary works of a large city.

The pay of the post will be Rs.1,500/-p.m., rising to Rs.2,000/-p.m., by annual increments of Rs.50/-p.m., plus a motor-car allowance of Rs.100 per mensem. The appointment will be for a period of five years, which may be extended from time to time at the discretion of the Corporation. The appointment is subject to the Provident Fund, leave, and other service rules of the Corporation. At present eight and one-third per cent. of the salary is deducted every month as contribution to the Provident Fund, and an equivalent amount is contributed by the Corporation at the end of the year and is credited to the subscriber's account. The Fund accumulates at compound interest. The selected candidate must keep a motor-car. He may obtain an advance from the Corporation for purchase of a suitable car, recoverable by monthly instalments spread over three years, the whole amount still outstanding to be recovered in the event of his appointment terminating within three years.

Applications, stating age, qualifications and practical experience, together with copies of the most recent testimonials, and also stating relationship, if any, with the Mayor, Deputy Mayor, Councillors, Aldermen and the Officers of the Corporation, should be addressed to the Secretary, Corporation of Calcutta, and should reach him on or before the 13th February, 1927. *A copy* of the application should be forwarded to the undersigned by the 13th January, who will be glad to reply to enquiries and will arrange to interview candidates who appear most suitable at a date and place to be fixed hereafter.

The selected candidate before joining must satisfy the undersigned as to the state of his health.

If selected from outside India, he will be allowed a first-class passage to Calcutta, to be refunded to Corporation if he resigns appointment within two years. He must join within two months of receiving notice of appointment, and will receive half pay for period occupied by journey.

PRACTICES AND PARTNERSHIPS FOR SALE.

1. HOME COUNTY. — Delightful district. Old estab., unopposed Country PRACTICE worth nearly £1100 per annum, including panel of over 700 and transferable appts. about £200. Fees 2s. 6d. to 15s., medicine extra. Midwifery from 2 gns., 10 cases yearly. Nearest opposition 6 miles. Railway station in place. Excellent up-to-date house with 3 reception, 6 bedrooms, &c., and usual offices. Garden with tennis court and orchard of 2 acres. Garage for 2 cars. Rent on lease (19 years to run) £120. Premium 1½ years' purchase.
2. LONDON, S.W.—Riverside Suburb.—Old-estab., non-panel, non-dispensing, Upper Middle-class PRACTICE, producing an income of over £3000 p.a. Fees from 7s. 6d. to 21s. About 12 Midwiferies yearly from 7 gns. upwards. Good house with 3 reception, 6 bedrooms, &c.; on long lease; rent £180. Good garden. Garage. Prem. £6000.
3. SOUTH AFRICA (Cape Province).—Well-estab. PRACTICE in a small Town with large surrounding district in an ideal climate, equable, sunny and dry and suitable for anyone in delicate health. Receipts last year over £700. Opposition not strong. Small pleasant bungalow residence on lease at a rent of £85 10s. p.a. Prem. £500.
4. GOOD HOSPITAL TOWN, within a few miles of the borders of Herefordshire.—Old-estab. mainly good-class non-dispensing PRACTICE. Income over £1400, including about £130 from appts. and panel of 450. Consultations 5s. to 10s. 6d.. Visits 7s. 6d. to 2 gns. Little Mid. Good house in centre of town, with ¼ of an acre of garden. Price freehold £1500. Prem. £2000. Exceptional scope for surgery.
5. SOUTH WALES COAST.—Hospital Town.—PARTNERSHIP.—A One-third Share, producing an average income of over £1550, is for disposal in an old-estab. Mixed-class Practice. Total panel of 2700, and appts. worth about £100. Fees 3s. 6d. to 5s., with medicine extra. Midwifery from 3 gns.: 35 to 40 cases yearly. Good house with separate entrance to professional rooms. Price for leasehold (over 60 years) £1800, part on mortgage. Sport of all kinds. Premium for share £1700.
6. MANCHESTER.—RESIDENTIAL SUBURB.—Old-estab. non-dispensing, non-panel PRACTICE. Steady average income of over £1250 with scope. Fees 3s. 6d. to 12s. 6d. No Midwifery. Good well-situated corner house. Garage. Garden. Freehold, price £2900. Prem. 1½ years' purchase.
7. CHESHIRE.—Non-dispensing and non-panel PRACTICE situated in a small pleasant country town of 10,000 inhabitants, and worth for last financial year £700. Vendor is a lady doctor, but states it is equally suitable for a medical man. Opposition very weak. Visits 5s. to 21s. Midwifery discouraged. House contains consulting, dining and drawing rooms, 4 bedrooms, bathroom, &c. Small garden. Would be let on lease at £90 p.a. Price for practice £1000. Good future propects.
8. MOROCCO.—Coast Town. — Mixed General PRACTICE producing an income of about £1000 p.a. Fees from 6s. 6d. to 2 gns. No Midwifery. Very low expenses. Excellent social and sporting facilities. Ideal climate. Convenient house, Can be rented at £66 p.a. Prem. to include goodwill, all furniture and fittings, drugs and equipment, &c., £1500.
9. PARTNERSHIP.—Pleasant Residential district within 12 miles of London. Owing to the retirement through ill-health of one of 3 partners, a well-qualified gentleman (30 to 35 years of age). can acquire a third Share in a very old-estab. Practice worth last year nearly £6000, including appts. and panel of 1500. Patients all classes. Visits 5s. to 21s., medicine mostly extra. Mid. 3 to 20 gns., 50 cases yearly. Suitable house available. Rent £140. Premium £4000. Cottage Hospital. Good society. Educational facilities, golf, tennis, &c.
10. CORNWALL.—Country PRACTICE.—Very old-estab., and patients are chiefly agricultural. Income for the immediate past year nearly £1400, including panel of about 750. Lowest fee 5s. Convenient house with 2 reception, 5 bedrooms, &c., surgery and waiting-room; rent on long lease £45 p.a. Sport of all kinds. Premium £1850, £1500 down and balance as arranged.
11. SOUTH CORNWALL.—Very attractive small Coast Town —Old-established General PRACTICE. Income last year over £1400, including £60 from appointments. Panel of between 400 and 500. Fees 2s. 6d., 5s. to 21s. About 20 cases of Midwifery yearly at 3 to 7 guineas. Well-situated semi-detached house with 2 reception and 7 bedrooms; small garden. Price £1600. Premium £2000.
12. RESIDENTIAL SUBURB (South of Thames).—Very old-established and mainly Homœopathic PRACTICE held 26 years. Cash receipts average about £1300 p.a., including panel of 270. Visits 5s. upwards (few at 3s. 6d.). Midwifery 3 to 4 gns.; few cases yearly. Very good house with ample accommodation and standing in one-third acre of ground; rent on lease £100 p.a. Prem. £1800. Scope.
13. PARTNERSHIP.—LONDON, N.W.—Pleasant Suburb.—Third share of old-established Mixed-class Practice, worth last financial year nearly £2500, including panel (increasing) of 3050. Visits 3s. 6d. to 10s. 6d. Midwifery for the past 12 months refused. Expenses light. Suitable accommodation (7 rooms) available for ingoing partner; rent £52 a year, including rates and taxes. Premium £1500.
14. NEAR PETERBOROUGH.—Well-established unopposed PRACTICE, producing an income of about £2000 a year, including panel of 1400 and appointments. Commodious house with 2 reception and 7 bedrooms, professional rooms, &c. Large house with two acres of ground, tennis court. It is in good repair and can be rented at £100 per annum. Very suitable for active man, or two friends in partnership. Premium 1½ years' purchase. Ill-health reason for sale.
15. EASTERN COUNTY. — Near Coast. — Old-established Better- and Mixed-class PRACTICE. Steady average income for last 3 years of £2000, including panel of nearly 1600. Fees 2s. 6d. to 10s. 6d. Very good house with 3 reception and 6 bedrooms, attics, &c. Separate entrance to surgery and waiting-room. In own grounds of 4½ acres. Garage. Price for freehold £3000, half of which could remain on mortgage. Premium £3000.
16. SURREY.—In a beautiful residential district within 40 miles of London (good train service), a small good-class PRACTICE worth between £600–700 p.a., and offering scope. Midwifery refused and panel not encouraged. Charming house, with ample accommodation, in very pretty grounds of nearly 5 acres. Price freehold £4500, or less with reduced acreage. Premium 1½ years' purchase.
17. LONDON, S.W.—Open Residential Suburb.—Old-estab. Middle-class non-panel PRACTICE, held over 20 years by Vendor. Receipts for past 3 years average £2063 p.a. Visits 5s. 6d. to 10s' 6d. Mid. 5 and 6 gns; under 10 cases yearly. Good corner residence (non-basement) with 11 rooms, bathroom, &c., and small garden. Held on exceptionally long lease at the very low rental of £60 p.a. Prem. £3350. Efficient introduction. Satisfactory reasons for selling. The practice is considered eminently transferable, and there are good prospects of increase.
18. PARTNERSHIP.—MIDLANDS.—In prosperous district, with pleasant surrounding country, the Third Share, producing about £700 p.a., which will be guaranteed, of an old-estab. increasing Practice, is for disposal. Panel nearly 2000. Patients middle- and working-class. Very nice house, in good repair, containing 2 recept., 4 bedrooms, bathroom, &c.; nice garden, rent on lease £40 p.a. Prem. £1400, half down and balance as arranged.

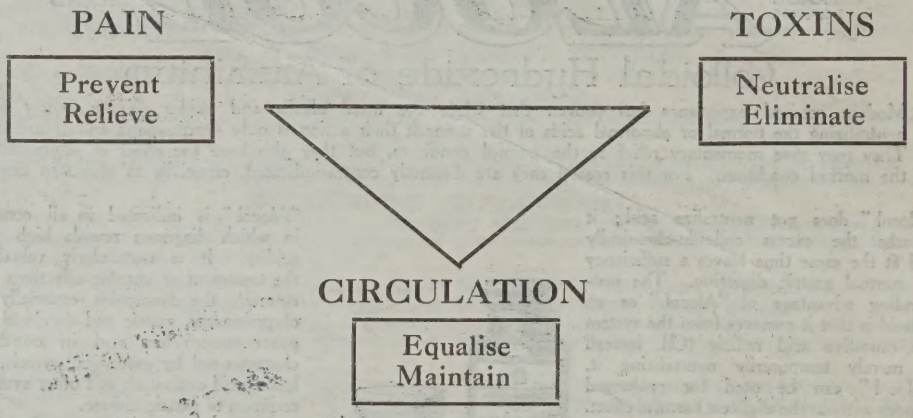
WANTED TO PURCHASE.

1. LONDON, W. or S.W.—Cash and Panel PRACTICE producing about £2000 a year, Convenient house with 5 or 6 bedrooms, preferably on rental.
2. RESIDENTIAL SUBURB OF LONDON.—Better-class PRACTICE, Income from £1800 to £2000 p.a. Good house and garden and garage for 2 cars if possible.
3. SOUTH OF ENGLAND.—PARTNERSHIP in Upper Middle-class Practice, offering good scope for surgery and chance of Hospital appt. Income about £1200.
4. LONDON or SUBURBS.—PRACTICE of about £1000. having panel of 1500. Small house. Capital £2000.

Profits accruing to Bovril, Ltd., from the Agency will be allocated amongst recognised Medical Charities.

Full Schedule of Terms and Conditions will be forwarded on application.

THE TRIAD OF TREATMENT IN PNEUMONIA



Authorities assert that the symptomic treatment of Lobar Pneumonia calls for applied heat for the pain and congestion, to ease cardiac activity, augment superficial circulation with resultant contraction of deep blood vessels, and to promote neutralisation and elimination of toxins.

Dyspnoea, restlessness and insomnia are relieved—temperature reduced.

Antiphlogistine
TRADE MARK

is a scientific remedy, harmless, soothing and non-toxic, evolved and perfected through chemical and physical research based upon practicability. It has been used with excellent results in Pneumonia and congestive and inflammatory conditions for 33 years by thousands of progressive physicians.

APPLICATION—spread Antiphlogistine warm and thick over entire chest and cover with cotton-wool jacket. Repeat in about 24 hours.

We will gladly send you a regular package with interesting and valuable booklet. This is free.
